VTLUs.....	27
VNX DDAR support feature.....	27
FileMover file system backup with NDMP.....	27
File system backup with NDMP using an integrated SnapSure checkpoint.....	28
Backup/restore with NVB.....	29
NVB requirements.....	31
NVB restrictions.....	32
Filter to exclude directories or files from backup.....	32

Valid path rules to exclude directories from backup.....	33
Valid file-pattern rules to exclude files from backup.....	34
Tape silvering.....	34
Planning considerations.....	34
Data Mover-to-TLU cabling examples.....	35
Implement international character support with NDMP.....	36
NDMPcopy.....	37
NDMP last access time.....	42
Multithreaded backup and restore design.....	42
<b>Chapter 3: Configuring.....</b>	<b>45</b>
Configure Data Movers .....	46
Configure the tape buffer size.....	46
Configure the read or write block size.....	47
Configure an NS series Data Mover.....	47
Configure Data Movers for international character sets.....	48
Override the autonegotiated NDMP version.....	49
Configure the Data Mover to increase the NDMP sessions (Optional).....	50
Configure the NDMP port range.....	51
Set up the TLU.....	53
Configure stand-alone tape drives.....	56
Configure VTLUs.....	56
Assign a username and a password to a Data Mover.....	56
With NIS.....	57
Without NIS.....	57
Set environment variables.....	58
<b>Chapter 4: Managing.....</b>	<b>63</b>
Manage backup parameters and statistics.....	64
View backup parameters.....	64
View a specific parameter.....	66
View all parameters.....	67
Modify parameters.....	69
View backup statistics.....	70
Reset backup statistics.....	73
Back up a VDM file system with NDMP.....	74
Back up a FileMover file system with NDMP.....	74
Restore a FileMover file system.....	75

Back up a file system with NDMP by using an integrated SnapSure checkpoint.....	75
Perform backup and restore with NVB.....	75
Specify NVB in backup vendor software.....	76
Perform NVB restores.....	77
Perform full destructive restore.....	77
Perform a full destructive restore of a VDM file system.....	85
File-level restore.....	85
Exclude directories or files from backup by using filtering.....	86
Exclude a directory.....	86
Exclude a file.....	88
Perform tape silvering.....	88
Restore with NetBackup.....	89
Restore with CommVault Galaxy.....	93
Restore with NetWorker.....	95

## Preface

*As part of an effort to improve and enhance the performance and capabilities of its product lines, EMC periodically releases revisions of its hardware and software. Therefore, some functions described in this document may not be supported by all versions of the software or hardware currently in use. For the most up-to-date information on product features, refer to your product release notes.*

*If a product does not function properly or does not function as described in this document, please contact your EMC representative.*

---

## Special notice conventions

EMC uses the following conventions for special notices:

---

Note: Emphasizes content that is of exceptional importance or interest but does not relate to personal injury or business/data loss.

---

 Identifies content that warns of potential business or data loss.

 Indicates a hazardous situation which, if not avoided, could result in minor or moderate injury.

 Indicates a hazardous situation which, if not avoided, could result in death or serious injury.

 Indicates a hazardous situation which, if not avoided, will result in death or serious injury.

---

## Where to get help

EMC support, product, and licensing information can be obtained as follows:

Product information—For documentation, release notes, software updates, or for information about EMC products, licensing, and service, go to EMC Online Support (registration required) at <http://Support.EMC.com>.

Troubleshooting—Go to EMC Online Support at <http://Support.EMC.com>. After logging in, locate the applicable Support by Product page.

Technical support—For technical support and service requests, go to EMC Customer Service on EMC Online Support at <http://Support.EMC.com>. After logging in, locate the applicable Support by Product page, and choose either **Live Chat** or **Create a service request**. To open a service request through EMC Online Support, you must have a valid support agreement. Contact your EMC sales representative for details about obtaining a valid support agreement or with questions about your account.

---

Note: Do not request a specific support representative unless one has already been assigned to your particular system problem.

---

---

## Your comments

Your suggestions will help us continue to improve the accuracy, organization, and overall quality of the user publications.

Please send your opinion of this document to:

[techpubcomments@EMC.com](mailto:techpubcomments@EMC.com)

The Network Data Management Protocol (NDMP) allows you to control the backup and recovery of an NDMP server through a network backup application, without installing third-party software on the server. In an EMC VNX, the Data Mover functions as the NDMP server.

This document explains how to perform NDMP backups with VNX and your backup software. It also contains the information you need to cable and configure VNX. Use this and other VNX documentation in conjunction with the specific backup software documentation provided by your vendor. [Chapter 2](#) provides more details.

This document is part of VNX documentation set and is intended for the backup system administrator implementing a backup strategy with one or more VNX. The system administrator should be familiar with backup and restore operations and with the basic administration of VNX.

Topics included are:

- ◆ [System requirements on page 12](#)
- ◆ [Restrictions on page 12](#)
- ◆ [Cautions on page 15](#)
- ◆ [User interface choices on page 15](#)
- ◆ [Related Information on page 16](#)

## System requirements

Table 1 on page 12 describes the EMC® VNX™ software, hardware, network, and storage configurations.

Note: VNX supports NDMP version 4.0.

**Table 1. System requirements**

Software	VNX version 7.1 NDMP-compliant backup software running on the NDMP client. <i>VNX for File Release Notes</i> contain a current list of the EMC qualified NDMP backup software vendors.
Hardware	VNX
Network	Dedicated network (optional)
Storage	Compatible tape device or tape library unit (TLU)

## Restrictions

Note these restrictions when configuring VNX.

### General restrictions

- ◆ EMC supports NDMP drive sharing only through a storage area network (SAN).
- ◆ VNX uses port 10000 for NDMP operations. NDMP three-way backups and restores use dynamic port allocation from the Data Mover.
- ◆ If you plan to turn on internationalization, do so before, not after creating the file systems.
- ◆ Stripe size on the system can affect backup performance. For optimal backup stripe size settings on EMC Symmetrix® and EMC VNX for block systems, consult the EMC E-Lab™ Interoperability Navigator.
- ◆ VNX supports a maximum of eight concurrent NDMP sessions per NDMP-Host Data Mover. The backup client (DMA) should be compatible and configured to support up to eight concurrent NDMP sessions.

- ◆ The Data Mover must have a minimum of 8 GB memory to run greater than four and up to eight NDMP sessions.
- ◆ For backups with VNX, a media interface adapter (MIA) for device connection to the AUX-0 port is required. For backups with VNX series, a small form-factor pluggable (SFP) adapter is required. Instructions on installing an MIA in VNX, or an SFP in VNX series, are documented in individual setup instructions provided with each system.
- ◆ Make sure that no backup or restore jobs are running on the Data Mover before you issue the `nas_fsck -aclchk` command.
- ◆ If a Data Mover is in ASCII mode and you back up a file system with `asciifilter` off, the filename with international characters cannot be recovered if the `asciifilter` is turned on during the restore. It is recommended that all Data Movers be configured to use UNICODE rather than ASCII mode.

*Configuring and Managing CIFS on VNX* provides information on how to check and change the Data Mover mode. *Using International Character Sets on VNX for File* provides information on enabling Unicode on a new VNX.

---

### Restrictions for TLU connections

- ◆ Do not connect the Control Station to the TLU. Only Data Movers can be connected to the TLU.
- ◆ Connecting multiple Data Movers to the same TLU is supported.
- ◆ If an NDMP-Host Data Mover fails over to its standby, you must physically connect the Data Mover's TLU cable to the standby, and restart the backup. You could also need to reconfigure the backup software with the appropriate address.

---

### NDMP restrictions

- ◆ NDMP does not support the Archive Bit method. Only the Date/Time stamp method is supported.
- ◆ The special wildcard characters, as well as the include/exclude options, are not supported. To back up multiple directories, include all directories in the file/directory list when creating the backup job. You can use filtering to exclude specific files and directories from a backup, as described in [Exclude directories or files from backup by using filtering on page 86](#).
- ◆ NDMP does not follow symbolic links among file systems. Therefore, an NDMP backup does not include a symbolic link's target file system. *Managing a Multiprotocol Environment on VNX* contains more information on symbolic links.

- ◆ NDMP backups and restores of iSCSI LUNs are not supported.
- ◆ Do not convert a raw file system (rawfs) that is created for NVB full destructive restore to uxfS file system, until the restore operation is completed successfully.

---

## Cautions

If any of this information is unclear, contact your EMC Customer Support Representative for assistance:

- ◆ If a failover occurs during a backup, you must directly connect the tape drive to the new Data Mover and restart the backup. You could also need to reconfigure the backup software.
- ◆ Do not unmount a target file system during a backup or restore operation.
- ◆ If you change the network zoning configuration, where relevant, propagate changes to the consistent binding table and adjust the backup software to reflect the new zoning configuration.
- ◆ In VNX for block environment, before you run the `server_devconfig -create` command, verify that all paths to the Data Mover are active and no LUNs are trespassed.
- ◆ You cannot back up tree quotas from the original file system and restore them to a different file system because the action is not supported. To preserve tree quotas when restoring, the target file system must be the same destination as the original file system, and it must have tree quotas enabled on it.

---

## User interface choices

VNX offers flexibility in managing networked storage that is based on your support environment and interface preferences. This document describes how to configure NDMP backups by using the command line interface (CLI). You can also perform some of these tasks by using one of the VNX management applications:

- ◆ EMC Unisphere™
- ◆ Microsoft Management Console (MMC) snap-ins
- ◆ Active Directory Users and Computers (ADUC) extensions

You cannot use the Unisphere software for:

- ◆ Creating NDMP user accounts
- ◆ Viewing PAX statistics when performing backups
- ◆ Configuring server devices

---

Note: You can use any secure, encrypted, remote login application to perform the NDMP management tasks above by running the appropriate CLI-based command.

---

For additional information about managing VNX:

- ◆ *Learning about VNX*
- ◆ Unisphere online help
- ◆ Application's online help system in the VNX Documentation on EMC Online Support

The *Installing Management Applications on VNX for File* document includes instructions on launching the Unisphere software, and on installing the MMC snap-ins and the ADUC extensions.

---

### **EMC VNX documentation on EMC Online Support**

The complete set of EMC VNX series customer publications is available on EMC Online Support. To search for technical documentation, go to <http://Support.EMC.com>. After logging in to the website, click **Support by Product** and type **VNX series** in the Find a Product text box. Then search for the specific feature required.

NDMP allows you to control the backup and recovery of an NDMP server through a network backup application, without installing third-party software on the server. On VNX, the Data Mover functions as the NDMP server.

NDMP-based backups are used for high-capacity backups and in environments where multiprotocol support is required. The NDMP protocol separates the control and data transfer components of a backup or restore operation. The actual backups are handled by the Data Mover, which minimizes network traffic.

For successful backup and restore, the length of the path including the filename should not have more than 4,095 bytes.

---

Note: Configuration options differ depending partly on the backup software and TLU manufacturer.

---

This section presents an overview of these NDMP configurations:

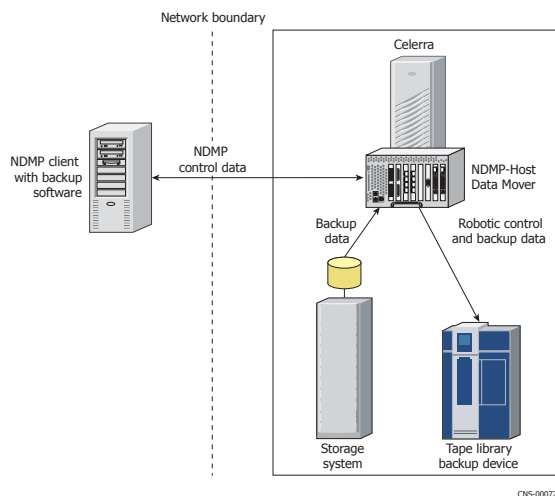

- ◆ [Basic NDMP backup configuration on page 21](#)
- ◆ [Single TLU configuration on page 22](#)
- ◆ [Dual TLU configuration on page 22](#)
- ◆ [Three-way backup configuration on page 23](#)

- ◆ Multithreaded backup and restore design on page 42

## Basic NDMP backup configuration

The NDMP architecture uses a client/server model in which the backup software is the NDMP client to the NDMP-Host Data Mover, as shown in [Figure 1 on page 21](#). Backup data flows from the system to the Data Mover to an attached tape library backup device, without traversing the network. Only the backup software's control data, such as scheduling, cataloging, and TLU commands, travel across the network.

The Data Mover maintains a state machine for each NDMP client connection that executes and maintains the backup and restore processes. A maximum of eight simultaneous NDMP sessions are supported on each NDMP-Host Data Mover. Each Data Mover supports up to eight concurrent NDMP sessions at one time. For example, server\_2 can run four backup sessions and four restore sessions simultaneously.

**Figure 1. Basic NDMP backup**

**Note:** Optionally, you can configure a Data Mover to serve as a VTLU and provide disk storage for backups, eliminating the need for a physical TLU. *Configuring NDMP Backups to Disk on VNX* explains how to create a VTLU on the Data Mover.

## Single TLU configuration

Figure 2 on page 22 demonstrates the first and most common TLU configuration. When a TLU configuration consists of several Data Movers sharing one robot, only one Data Mover needs to be connected to the robot. One Data Mover can execute backups and robot operations. Robotic commands are executed from the backup software.

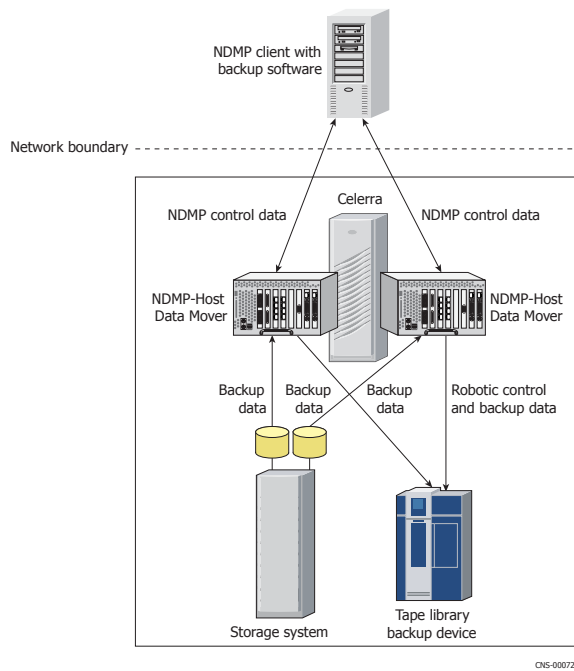

Figure 2. Single TLU NDMP backup

## Dual TLU configuration

Figure 3 on page 23 shows two Data Movers connected to two separate storage system volumes with two separate tape-library-backup devices. The NDMP client controls and launches the backup. The Data Mover processes the data and sends it to the tape device.

Figure 3. Dual TLU NDMP backup

## Three-way backup configuration

You can direct backup data from one Data Mover, which is the NDMP backup host, through a network connection to a remote NDMP tape server to its attached tape backup device, with NDMP version 2.0 and later, and some backup software products provided by your vendor. The NDMP tape server can be a Data Mover or another qualified server. This configuration is known as three-way backup.

Three-way backup involves these hosts:

- ◆ NDMP backup client running qualified NDMP backup software
- ◆ Data Mover (NDMP data server) containing the data to be backed up (reads from the system and produces a datastream for backup)
- ◆ Data Mover or qualified server running the tape service (reads the datastream and writes it to tape)

---

Note: VNX supports heterogeneous three-way backups with the EMC-qualified backup vendors listed in the E-Lab Interoperability Navigator.

---

In a three-way backup configuration, backup data and control data travel across the network. This connection can be a dedicated network to avoid network traffic. [Figure 4 on page 24](#) illustrates a Data Mover-to-Data Mover, three-way backup.

Figure 4. Three-way NDMP backup

## Backup levels with VNX and NDMP

A token-based incremental backup uses the `BASE_DATE` and `DUMP_DATE` environment variables to invoke full and incremental backups. In a token-based backup, the NDMP client, rather than the Data Mover, maintains the database of backup timestamps, which are used to identify files that should be included in incremental backups. The `BASE_DATE` environmental variable specifies the incremental count field and the date/time of a previous backup, and this information serves as the base for a current incremental backup. The NDMP client never computes the value of `BASE_DATE`. Rather, the NDMP client either sets the `BASE_DATE` by using the `DUMP_DATE` it receives from the NDMP server after a previous backup of the same path, or it sets the `BASE_DATE` to zero, thus requesting a full backup.

The `DUMP_DATE` environment variable specifies the dump-date token for the current backup operation. At the end of a successful backup operation, the NDMP client should retrieve the `DUMP_DATE` environment variable. It retrieves this variable by issuing an `NDMP_DATA_GET_ENV` request while the NDMP data server is in a halted state. `DUMP_DATE` is returned only if `BASE_DATE` was previously specified by the NDMP client as part of the backup environment. When `BASE_DATE` is specified, the `LEVEL` environment is ignored.

NDMP defines 0–9 for dump levels, with level 0 being a full backup. For incremental-backup levels 1–9, only changes since the next available lower-level incremental backup or since a full backup are copied. VNX NDMP supports level 10, which allows any number of incremental backups. It backs up all files modified since the most recent backup, which can be a level 10 or lower, if no level 10 backup was run previously.

## NDMP V4 IPv6 Extension for VNX

The NDMP V4 IPv6 Extension for VNX facilitates the NDMP backup by using Internet Protocol version 6 (IPv6) in addition to the existed support of IPv4. When a data connection between two servers is created using TCP/IP, the NDMP requests/responses can include both IPv4 and IPv6 address types.

IPv6 has a vastly larger address space than IPv4. IPv6 uses a 128-bit address, thus supports  $2^{128}$  (about  $3.4 \times 10^{38}$ ) addresses. This expansion provides flexibility in allocating addresses, routing traffic, and eliminates the primary need for network address translation (NAT). VNX and DMA needs to be configured to support IPv6 in order to use this feature.

## Restore PAX file systems

A restore reverses the backup process shown in [Basic NDMP backup configuration on page 21](#). This operation, initiated by the backup software, retrieves the data from the backup device, sends it to the Data Mover, and restores the data on the system. The benefit of the NDMP backup and restore is that it has no traffic impact on the data network.

**Note:** VNX database on the Control Station cannot be backed up to tape by using NDMP backup. Rather, this database is backed up automatically each hour by a script running on the Control Station. It can also be backed up manually, as described in *VNX System Operations*, and moved to a safe, remote location by using the File Transfer Protocol (FTP), as described in *Using FTP, TFTP, and SFTP on VNX*.

Restoring space-reduced files from a PAX-based NDMP backup into a file system causes the deduplication state to be set to suspended if the deduplication state is not currently enabled. *Using VNX File Deduplication and Compression* provides more information.

**Note:** You cannot restore deduplicated files from an NDMP backup performed on a system that is running VNX OE 7.1.47.5 or later to a system running version 5.6.46 or earlier.

## Dynamic drive sharing

Several backup software vendors are developing the ability to allow more than one NDMP-Host Data Mover to share single or multiple tape drives. The backup software controls the ability of the NDMP-Host Data Movers to share the tape drives and mediates the negotiation for tape-drive access during simultaneous backups. EMC supports sharing tape drives over a SAN as shown in [Figure 5 on page 26](#).

**Figure 5. Dynamic drive sharing**

---

## VTLUs

A VTLU is a software-based TLU that resides on a Data Mover and emulates a physical TLU. It is also known as NDMP2D. A VTLU allows for compatibility between NDMP and disk-based storage. The NDMP-compliant backup software cannot distinguish between a physical TLU and a VTLU. This allows you to manage the VTLU as if it were a physical TLU. *Configuring NDMP Backups to Disk on VNX* provides more information on VTLUs.

---

## VNX DDAR support feature

The enhanced DAR functionality, called DDAR, optimizes the data recovery operation by allowing the NDMP client to directly access backed-up data anywhere in a tape set without having to traverse the tape set sequentially. This method can save significant time in the restore operation. DDAR is realized only when you use EMC-qualified backup vendor software that fully supports DDAR. The EMC E-Lab Interoperability Navigator lists the EMC-qualified vendors supporting DDAR for this release.

Other improvements include enhancements in the PAX DUMP format incremental backup operation, and the three-way DAR restore operation. With DUMP incremental backups, only the changed files and the directories leading up to them are backed up, and this could save a lot of tape space for a big file system. The three-way DAR performance enhancement changes the way the data is acquired, and can dramatically improve the performance regarding small files. No environmental variable changes are required to realize these enhancements.

---

## FileMover file system backup with NDMP

VNX FileMover-enabled file system, used in conjunction with external policy migration software, automatically migrates infrequently used files to less-expensive secondary storage systems. VNX is the primary data storage system, while the secondary system might be another VNX or a network file server supporting CIFS or NFS.

When a file migrates to secondary storage, the file contents migrate to a file on secondary storage and the original file is converted to a stub file. The stub file contains all the metadata of the file including its actual location on secondary storage to ensure that VNX can locate and recall the file data as needed.

When you back up a FileMover-enabled file system by using NDMP, you have the choice of backing up only the content on primary storage, including stub files. Or you can back up the content on primary and secondary storage, which also includes the content to which the stub files point. By default, only the primary storage content is included in an NDMP backup. The stub files on the primary system that include only file metadata are backed up without the file content. To include the file system content on primary and secondary storage in an NDMP backup, set the environment variable `EMC_OFFLINE_DATA=y` in the backup software. This variable must be set before you perform a backup to ensure that the backup contains all file system data from primary and secondary storage.

## File system backup with NDMP using an integrated SnapSure checkpoint

Creating a checkpoint using EMC VNX SnapSure™ in the backup process lets you back up a consistent, point-in-time image of a live file system without halting activity on the file system during the backup process.

In earlier versions, using a checkpoint for a backup required that you create a checkpoint prior to running NDMP, possibly manage the checkpoint during the backup, and then delete the checkpoint when the backup completed. These manual tasks were required each time you initiated an NDMP backup. The backup failed if the Production File System (PFS) was mounted as read-only.

With version 7.0 and later, backup using integrated checkpoint supports a read-only file system or its subdirectory as the backup root. You can automate the checkpoint creation, management, and deletion activities by setting the SNAPSURE=y environmental variable to y in the qualified vendor backup software. The E-Lab Interoperability Navigator lists the backup software vendors that support the SNAPSURE=y environmental variable. This integrated checkpoint feature can be used with other EMC backup features, such as NVB and File Filtering.

If the backup software does not support the SNAPSURE=y environmental variable, you can set the parameter NDMP.snapsure in the Data Mover to use VNX SnapSure for backup. The default parameter value 0 should be changed to 1. You must ensure that the variable SNAPSURE=n is not set on the backup software. The SNAPSURE=n variable overrides the NDMP.snapsure parameter.

When the SNAPSURE=y variable is set in the backup software, and then each time you run a particular job a checkpoint of the production file system is automatically created and mounted as read-only, before the NDMP backup starts. The checkpoint is automatically used for the backup, allowing production activity to continue uninterrupted on the file system. During the backup process, the checkpoint is automatically managed (for example, autoextended if needed, space permitting). And when the backup completes, regardless of whether the operation succeeded or failed, the checkpoint is automatically deleted.

A checkpoint cannot be backed up by using the integrated checkpoint feature. You can back up only the checkpoint of an IP replication read-only target file system by using the NDMP backup feature. If you back up a replication read-only target file system, NDMP will fail when replication is updating the change.

For the checkpoint to be automatically created and deleted in the backup process, the Data Mover needs to communicate with the Control Station, which is the normal operation.

The checkpoint that is automatically created in the backup process is given a unique, system-defined name that appears in the automaticNDMPCkpts directory, and in the checkpoint list for VNX SnapSure, as follows:

```
automaticTempNDMPCkpt<id>-<srcFsid>-<timestamp>
```

where:

<id> = checkpoint ID

`<srcFsid>` = ID of the source file system being backed up using the checkpoint

`<timestamp>` = date and time of checkpoint creation

Checkpoints with this name are for NDMP use only and must not be unmounted, refreshed, or deleted.

VNX supports a maximum of eight concurrent NDMP sessions for each Data Mover and 2048 checkpoints per file system. The checkpoint that is created in each NDMP session counts toward the maximum number of checkpoints per file system. When the backup process completes, the checkpoint is autodeleted and as with any checkpoint deletion, the checkpoint count is reduced by one. *Using VNX SnapSure* and *Using VNX Replicator (V2)* provide more details on checkpoints.

Each time an NDMP checkpoint is created or deleted, the cmd log is modified with the updated information. The autogenerated checkpoint uses the naming convention:

```
automaticTempNDMPckpt<id>-<srcFsid>-<timestamp>
```

 **CAUTION** If, for any reason, the checkpoint is not created or mounted, the NDMP backup fails.

When the backup completes, the checkpoint is unmounted and then deleted along with its mount point. The integrated checkpoints are transparent and require no administration.

## Backup/restore with NVB

VNX NVB is an EMC-specific type of NDMP backup mechanism that backs up data blocks at a volume level, rather than at a file level. NVB reads a set of disk data blocks in an efficient manner compared to the method used for traditional, file-based backups. NVB works only with EMC-qualified vendor backup software, as listed in the E-Lab Interoperability Navigator. *VNX for File Release Notes* contains late-breaking administrator support information.

---

Note: For NVB, volume refers to the entire metavolume associated with a file system.

---

NVB can be used when performing a full backup or an incremental backup. And as discussed later in this section, the mechanism also supports two types of restore: full destructive restore, which delivers the best possible write performance, and file-level restore.

As shown in [Figure 6 on page 30](#), VBB uses the NDMP protocol to interface with backup administration clients, yet it is completely different from the PAX (tar or dump) types of backup. You must specify the VBB backup type before you initiate the backup to invoke VBB functionality. When HIST=y, the environmental variable is enabled in the backup vendor's software. The VBB feature creates a file history that appears similar to one created by the dump backup type.

**Figure 6. Invoking NVB**

VNX File Deduplication and Compression-enabled file systems can be backed up by using NVB and restored, using the full destructive restore (FDR) method. Backing up a deduplicated file system does not cause any data reduplication, because NVB operates at the block level (while preserving the history of the files it backs up). The data in the file system is backed up in its reduced form. The benefits of the space-saving storage efficiency realized in the production file system, from compression and file-level deduplication, flow into backups. However, a file-by-file restore of space-reduced files from NVB backups is not supported. It is recommended that a file-by-file restore be performed by using local or remotely replicated checkpoints using VNX SnapSure, and not from tape.

## NVB requirements

NVB requires a read-only file system. Any of these options can be used to have a read-only file system as the source for an NVB:

- ◆ Use the Backup-with-Integrated-Checkpoints feature, which automatically creates, mounts as read-only, and uses the new checkpoint of the file system for the backup, and then deletes the checkpoint when the backup completes. [Back up a file system with NDMP by using an integrated SnapSure checkpoint on page 75](#) provides the related procedures.
- ◆ Manually create a new checkpoint using VNX SnapSure, or specify an existing checkpoint. Checkpoints are created and automounted as read-only file systems. *Using VNX SnapSure* explains the procedure.
- ◆ Manually create a new EMC TimeFinder<sup>®</sup>/FS snapshot, or specify an existing snapshot. Snapshots are created as read-only file systems. *Using TimeFinder/FS, NearCopy, and FarCopy on VNX* explains the procedure.
- ◆ Mount the file system as read-only.

---

## NVB restrictions

These restrictions apply when using NVB:

- ◆ NVB does not support selectively backing up a subset of the file system. For example, you can back up `ufs1`, but not `ufs1/dir1`.
- ◆ NVB and the File and Directory Filtering features do not work together. If both are specified, NVB overrides and the filters have no effect.
- ◆ NVB and DDAR functionality do not work together.
- ◆ If the File History variable is disabled, for example, `HIST=n`, then only full restores can be performed from an NVB backup. Also, individual files or directories cannot be restored.
- ◆ On FileMover-enabled file systems, NVB does not support the NDMP environment variable, `EMC_OFFLINE_DATA`. In this case, the contents of migrated files, the offline files, on secondary storage must be backed up independently.

---

## Filter to exclude directories or files from backup

Filtering for Backup Clients is a feature introduced with version 5.5 to enable specific directories and files within a file system to be excluded from an NDMP backup session, as needed. The filtering feature is implemented by using one or both of these environmental variables in the qualified backup-vendor software: `EMC_EDIR[01-50]` and `EMC_EFILE[01-50]`. File filtering is done based on the UNIX path. You can use these variables to exclude noncritical directories and files, such as `.mp3`, `.wma`, and `.temp`, from the backup session.

The benefits of using file and directory filtering include:

- ◆ Shorter backup Windows
- ◆ More flexibility to structure a backup session
- ◆ Efficient use of tape, that is, space is not consumed by non-critical data

The E-Lab Interoperability Navigator lists the EMC-qualified backup software vendors that currently support the environmental variables used for filtering.

---

**Note:** The filtering feature is supported only by NDMP PAX (dump or tar) backup types. Do not use file and directory filtering with the NVB.

---

Some examples of how the Filtering for NDMP Backup Clients feature can be used:

Example 1: A file system has one directory under `/ufs1` that contains a large amount of critical data in a database (`/ufs1/db`). It also has many other directories that contain non-critical data. You want to back up all the data, but on different schedules. To back up the critical data (`/ufs1/db`) every day, and then back up the less critical data once a week, you can exclude

the large database directory from the weekly backup by using the EMC\_EDIRXX environmental variable as follows:

```
EMC_EDIR01=/ufs1/db
```

Example 2: To back up ufs1 and exclude directory /ufs1/db, all .mp3 and .wma files, and all files with the prefix temp, set the variables as follows:

```
EMC_EDIR01=/ufs1/db
```

```
EMC_EFILE01=*.mp3
```

```
EMC_EFILE02=*.wma
```

```
EMC_EFILE03=temp*
```

Example 3: To back up ufs1 and exclude any files ending in the doc extension, and any files that begin with ab, set the variables as follows:

```
EMC_EFILE01=*doc
```

```
EMC_EFILE02=ab*
```

A file named abc.doc would be excluded from this backup.

---

## Valid path rules to exclude directories from backup

Follow these rules to specify the valid path:

- ◆ The path must start with a forward slash (/) and the file system name.
- ◆ The path can contain a maximum of 4,095 bytes.
- ◆ Supported wildcards are: question mark (?), which matches any single character, and asterisk (\*), which matches any sequence of zero or more characters.
- ◆ Users cannot use the question mark and asterisk wildcards on the same pattern.
- ◆ For directory filtering, the question mark and asterisk wildcards can appear only at the end of the string.

---

Note: The question mark wildcard is not accepted when VNX international character sets are enabled. A message is sent to the server log when this is attempted.

---

- ◆ The pattern-match algorithm is case-sensitive, by default. To make it case-insensitive, use the pax param filter.caseSensitive. The default value 1 should be changed to 0.

---

## Valid file-pattern rules to exclude files from backup

Follow these rules to specify a valid file-pattern:

- ◆ The file pattern can contain a maximum of 255 ASCII characters.
- ◆ Supported wildcards are: question mark (?), which matches any single character, and asterisk (\*), which matches any sequence of zero or more characters.

---

Note: The question mark wildcard is not accepted when VNX international character sets are enabled. A message is sent to the server log when this is attempted.

---

- ◆ Users cannot use the question mark and asterisk wildcards on the same pattern.
- ◆ For file filtering, valid wildcards can appear at the beginning or end of the string, but not both.
- ◆ The pattern-match algorithm is case-sensitive, by default. To make it case-insensitive, use the pax param filter.caseSensitive. The default value 1 should be changed to 0.

---

## Tape silvering

Copying the baseline source file system from the source to the destination site over the IP network can be a time-consuming process. You can use an alternate method by copying the initial checkpoint of the source file system, by backing it up to a disk array or tape drive, and by transporting it to the destination site. This method is known as silvering. *Using VNX Replicator (V2)* and [Perform tape silvering on page 88](#) provide more information.

---

Note: This special backup is used only for transporting replication data.

---

---

## Planning considerations

This section includes information on these considerations:

- ◆ [Data Mover-to-TLU cabling examples on page 35](#)
- ◆ [Implement international character support with NDMP on page 36](#)
- ◆ [Multithreaded backup and restore design on page 42](#)

## Data Mover-to-TLU cabling examples

This section includes examples of SCSI and Fibre Channel cabling from the Data Mover to the TLU. For more information on cabling a TLU to a backup host, check the backup software documentation provided by your vendor.

### SCSI cabling configuration

In [Figure 7 on page 35](#), two SCSI connections connect the NDMP-Host Data Movers to the TLU. One SCSI connection is daisy chained to two tape drives, and the other is daisy chained to two tape drives and a robot. All Data Movers in [Figure 7 on page 35](#) have two direct SCSI connections to VNX.

Figure 7. Sample SCSI cabling configuration

### Robot connectivity

If a configuration consists of several Data Movers sharing one TLU robot, you need to connect only one of these Data Movers to the robot. Robotic control is configured in the backup software. For more information on robotic control, consult the appropriate backup software documentation provided by your vendor.

### Fibre Channel configuration

[Figure 8 on page 36](#) shows the Fibre Channel connection from the system to a switch and from the switch to the top port of each Data Mover. The bottom port of each Data Mover connects to another switch through Fibre Channel, and from that switch to the TLU through Fibre Channel.

In a configuration where SCSI is used to connect to a TLU, the SCSI connection is achieved by connecting the second switch to a bridge through Fibre Channel, and then the SCSI cable connects the bridge to the TLU.

Note: You can use one switch by connecting the system and the TLU to the same switch. [Figure 8 on page 36](#) illustrates a two-switch configuration.

Figure 8. Sample Fibre Channel configuration

## Implement international character support with NDMP

VNX supports international character sets if you have Unicode enabled. VNX supports the architecture-independent UTF-8 Unicode format. This section includes these subsections related to performing NDMP backups with Unicode enabled:

- ◆ [Verify vendor support for international character sets on page 36](#)
- ◆ [Data backup-type behavior with international character sets on page 37](#)

Note: Unicode, once enabled, cannot be disabled.

### Verify vendor support for international character sets

Verify that the EMC-qualified NDMP backup software you chose supports international character sets. The backup software you chose with NDMP determines which of the two VNX implementations to follow:

- ◆ If your vendor supports international character sets, follow the vendor instructions for implementation and follow up with the backup software vendor regarding any issues you encounter.

You must set the Data Mover parameters for NDMP and for international character sets. [Configure Data Movers for international character sets on page 48](#) explains how to set the parameters for international character sets. *Using International Character Sets*

on *VNX for File* contains more information on how to use international character sets with VNX.

---

Note: The E-Lab Interoperability Navigator and the backup software vendor documentation list the EMC-qualified backup software vendors that support the use of international character sets.

---

- ◆ If your backup vendor does not support international character sets, choose the best translation configuration file for your environment, as described in *Using International Character Sets on VNX for File*.

If Unicode is enabled on the VNX, but your backup vendor does not support international character sets, you can set up your environment to work with the best translation configuration file for your environment. The default translation dialect is UTF-8. *Using International Character Sets on VNX for File* provides details about translation files and by choosing the appropriate file for your configuration. You must also set VNX parameters as specified in [Configure Data Movers for international character sets on page 48](#).

---

### Data backup-type behavior with international character sets

Data is backed up onto tape by using the tar, dump, or VBB NDMP backup type. If you have chosen a translation configuration file, the filename is converted to the client encoding and sent to the client as the file history. During an NDMP tar, dump, or VBB backup, if a file was created by using a character not appearing in the code page character set, or a file is found that the translation configuration file cannot translate, the file information that is a filename with a random inode number appended is sent to the backup client to provide file history. However, this filename cannot be used to restore the file. An error log is created and the remaining NDMP backup continues normally. Files with catalog information unable to be backed up can be recovered only through a full restore of the directory.

If a surrogate pair character is used as a folder name in the VNX file system from a CIFS client, or if the CIFS folder name is longer than 255 bytes with multibyte characters, the NDMP restore operation can change the folder name to UTF8ConversionError. UNIX names on VNX are set to UTF8ConversionError as the conversion is not supported. For example, a Japanese character can use 3 bytes per UTF-8 character. In the NDMP restore operation, DAR does not handle a parent folder, and we use UNIX parent directory instead of CIFS parent folder. Filenames can be restored easily. Use non-DAR full NDMP restore or NDMP DDAR restore for such CIFS folders and files.

---

## NDMPcopy

The NDMPcopy utility is an open source program that improves the rate of data transfer. It allows the user to copy file system data within the Data Mover or between different Data Movers that are on the same or different VNX. If the source and destination file systems are

on the same Data Mover, the data is transferred directly from the source to the destination file system without traversing and overloading the NDMPcopy host machine or network. The NDMPcopy utility uses the NDMP to transfer the file system data.

The NDMPcopy utility contacts the NDMP server processes on the source and destination Data Movers. It authenticates the connection, and initiates data transfers between the source and destination file systems. The NDMP host receives status messages only.

The NDMPcopy utility also provides multiprotocol (NFS/CIFS) support. It is recommended to use NDMPcopy for data transfer only. When using NDMPcopy to transfer files between data movers, the destination data mover must be running the same or later VNX operating environment (for File) version as the source data mover. The NDMPcopy utility can affect the scheduling of backup activities in the same source, as it modifies the BackupDates file on the Data Mover. It uses text mode for authentication and so the password will be sent across the network in a non-encrypted format.

---

Note: NDMPcopy does not require any backup application or tape device.

---

You can perform data transfers from the source to the destination file system, by using this format:

*Data Mover:/path*

where:

*Data Mover* = IP address of the Data Mover

*path* = pathname of the directory to be used for data transfer

---

### Prerequisites

- ◆ The NDMPcopy utility should be installed on the host machine.
- ◆ The two Data Movers can communicate with each other by using the ping command with hostnames or IP addresses that they need to contact as parameters. If the ping command does not work, the ndmpcopy command will hang. You can use the server\_ping and server\_route commands to detect and correct network problems.

---

### Examples

- ◆ To transfer data from the source to the destination, on the same Data Mover, use this command syntax:

```
# ndmpcopy Data_Mover_IP:/src_filesystem_path Data_Mover_IP:
/dest_filesystem_path -sa username:password -da username:password
```

where:

**-sa username:password:** specifies the username and password of the source Data Mover. The source Data Mover authentication is used to verify the network connections to the source Data Mover. You must specify the username and include a colon (:) after the username. If you do not type the password after "username:" in

the command line, the `ndmcopy` command will prompt you for the password. Use the `-dpass` option if the source and destination passwords differ, and if you do not want to type the password in the command line. The username and password should match the username and password that you typed for the source NDMP-Host Data Mover in [Assign a username and a password to a Data Mover on page 56](#).

---

**Note:** If the password is not configured on the source or destination Data Movers, the `ndmcopy` command will fail.

---

`-da username:password`: specifies the username and password of the destination Data Mover. The destination Data Mover authentication is used to verify the network connections to the destination Data Mover. Make sure you specify the username and include a colon (:) after the username. If you do not type the password after "username:" in the command line, the `ndmcopy` command will prompt you for the password. Use the `-dpass` option if the source and destination passwords differ, and if you do not want to type the password in the command line. The username and password should match the username and password that you typed for the source NDMP-Host Data Mover in [Assign a username and a password to a Data Mover on page 56](#).

---

**Note:** If the password is not configured on the source or destination Data Movers, the `ndmcopy` command will fail.

---

**Example:**

```
# ndmcopy 10.6.123.162:/server2_fs1 10.6.123.162:/server2_fs2 -sa
s2_user:s2_password -da s2_user:s2_password
```

**Output:**

```
Connecting to 10.6.123.162.
Connecting to 10.6.123.162.
10.6.123.162: CONNECT: Connection established.
10.6.123.162: CONNECT: Connection established.
10.6.123.162: LOG: server_archive: emctar vol 1, 16 files, 0 bytes
read, 279236 bytes written
10.6.123.162: HALT: The operation was successful!
Waiting for 10.6.123.162 to halt too.
10.6.123.162: LOG: server_archive: emctar vol 1, 16 files, 279236
bytes read, 0 bytes written
10.6.123.162: HALT: The operation was successful!
The transfer is complete.
```

- ◆ To transfer data from the source to the destination file systems that reside on different Data Movers:

```
# ndmcopy Source_Data_Mover_IP:/src_filesystem_path Destination_Da
ta_Mover_IP:/dest_filesystem_path -sa username:password -da user
name:password
```

**Example:**

```
# ndmcopy 10.6.123.162:/server2_fs1 10.6.123.164:/server3_fs1 -sa
s2_user:s2_password -da s3_user:s3_password
```

**Output:**

```

Connecting to 10.6.123.162.
Connecting to 10.6.123.164.
10.6.123.162: CONNECT: Connection established.
10.6.123.164: CONNECT: Connection established.
10.6.123.162: LOG: server_archive: emctar vol 1, 16 files, 0 bytes
read, 279236 bytes written
10.6.123.162: HALT: The operation was successful!
Waiting for 10.6.123.164 to halt too.
10.6.123.164: LOG: server_archive: emctar vol 1, 16 files, 279236
bytes read, 0 bytes written
10.6.123.164: HALT: The operation was successful!
The transfer is complete.

```

- ◆ To avoid typing the password in the command line:

```

# ndmpcopy 10.6.123.162:/server2_fs1 10.6.123.162:/server2_fs2 -sa
s2_user: -da s2_user:

```

**Output:**

```

Password:
Connecting to 10.6.123.162.
Connecting to 10.6.123.162.
10.6.123.162: CONNECT: Connection established.
10.6.123.162: CONNECT: Connection established.
10.6.123.162: LOG: server_archive: emctar vol 1, 16 files, 0 bytes
read, 279236 bytes written
10.6.123.162: HALT: The operation was successful!
Waiting for 10.6.123.162 to halt too.
10.6.123.162: LOG: server_archive: emctar vol 1, 16 files, 279236
bytes read, 0 bytes written
10.6.123.162: HALT: The operation was successful!
The transfer is complete.

```

- ◆ Use the `-dpass` option, as displayed in the output below, if the source and destination passwords differ, and if you do not want to type the password in the command line:

```

# ndmpcopy 10.6.123.162:/server2_fs1 10.6.123.164:/server3_fs1 -sa
s2_user: -da s3_user: -dpass

```

**Output:**

```

Source password:
Destination password:
Connecting to 10.6.123.162.
Connecting to 10.6.123.164.
10.6.123.162: CONNECT: Connection established.
10.6.123.164: CONNECT: Connection established.
10.6.123.162: LOG: server_archive: emctar vol 1, 16 files, 0 bytes
read, 279236 bytes written
10.6.123.162: HALT: The operation was successful!
Waiting for 10.6.123.164 to halt too.
10.6.123.164: LOG: server_archive: emctar vol 1, 16 files, 279236
bytes read, 0 bytes written
10.6.123.164: HALT: The operation was successful!
The transfer is complete.

```

- ◆ Use the `-h` option, as displayed in the output below, to get more information about the usage of `ndmpcopy` and help message:

```
# ndmpcopy -h
```

### Output:

```
Usage:
ndmpcopy src_filer:/src/dir dest_filer:/dest/dir
        [-sa none|user:password] [-da none|user:password]
        [-sport ndmp_src_port] [-dport ndmp_dest_port]
        [-dhost ndmp_dest_ip_addr] [-level ndmp_dump_level]
        [-v] [-q] [-dpass] [-h]

Defaults:
src_auth_type      = text
src_auth_user      = root
src_auth_password  =
dest_auth_type     = text
dest_auth_user     = root
dest_auth_password =
ndmp_src_port      = 0 (0 means NDMP default, usually
                    10000)
ndmp_dest_port     = 0 (0 means NDMP default, usually
                    10000)
ndmp_dump_level    = 0 (valid range: 0 - 9)
ndmp_dest_ip_addr  = (no default: user needs to
                    override dest_filer value)
verbosity          = noisy
different_passwords= no
```

You can also make use of these options, if required:

- ◆ **-dpass:** Use this option if the passwords for the source and destination Data Movers are not the same and if you do not want to specify the password on the command line.
- ◆ **-h:** Provides usage information and help message for NDMPcopy.
- ◆ **-sport (Optional):** Port address of the source Data Mover. The default value is 0, which is the NDMP default (10000). If you specify a value other than 0 or 10000, the transfer will fail.
- ◆ **-dport (Optional):** Port address of the destination Data Mover. The default value is 0, which is the NDMP default (10000). If you specify a value other than 0 or 10000, the transfer will fail.
- ◆ **-level (Optional):** The incremental level that can be set for the data transfer. You can set this value from 0 through 9. The default level is 0.

---

**Note:** If the source file system has not been modified after a level 0 copy, all other subsequent levels from 1 through 9 will fail until the source file system is modified.

---

- ◆ **-v (Optional):** The default value of verbosity is noisy.

## NDMP last access time

Last access time (atime) is not retained during NDMP backup/restore and NDMPcopy operations and it is set to the modification time (mtime). After a file migration, the user loses the ability to archive “cold” or “inactive” data. A new environmental variable RETAIN\_ETIME is added for the NDMP data stream to preserve the atime.

By default, the RETAIN\_ETIME is set to “N”. If the variable is set to the default value “N”, VNX will restore the file and apply the atime to mtime. When the RETAIN\_ETIME is set to “Y”, the atime is set as the last access time approximately. VNX then restores the file and applies the retained atime to the file.

To retain the atime during NDMP backup/restore, the data stream needs to be changed. A new field atime is added to the data stream headers. When the RETAIN\_ETIME environmental variable is set to “Y”, the value is logged in the server log as INFO message: NDMP:4:Name:RETAIN\_ETIME Value:Y

This feature is supported by the EMC Networker and Symantec NetBackup.

## Multithreaded backup and restore design

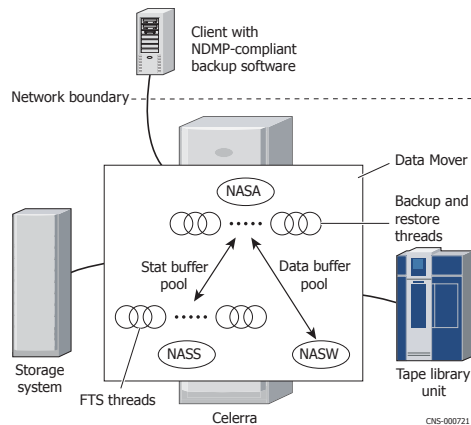

VNX uses a multithreaded backup and restore design that improves the VNX NDMP backup and restore performance in most environments. The design involves three main thread groups, referred to as NASA, NASS, and NASW. These thread groups process and deliver backup and restore data and metadata. [Table 2 on page 42](#) describes the function of each thread group. [Appendix A](#) provides a detailed description of the parameters related to multithreaded backup. The server\_pax command, presented in [View backup statistics on page 70](#), displays backup statistics for each thread group.

**Table 2. Backup thread groups**

Thread	Function
NASA	<ul style="list-style-type: none"> <li>◆ Sends metadata to the NDMP backup software</li> <li>◆ Reads file data</li> <li>◆ Writes data to the buffer pool</li> </ul>
NASS	<ul style="list-style-type: none"> <li>◆ Traverses the file system</li> <li>◆ Provides metadata for each file or directory</li> </ul>
NASW	<ul style="list-style-type: none"> <li>◆ Obtains data from the data buffer pool</li> <li>◆ Writes data to a tape or sends it to a remote Data Mover or NDMP server</li> </ul>

## Multithreaded backup process

When you initiate an NDMP backup, the NASA thread group activates multiple backup threads and puts metadata buffers in the stat buffer pool, which is shared by NASA and NASS. [Figure 9 on page 43](#) shows the components of the multithreaded design.

**Figure 9. Multithreaded backup and restore**

The stat buffer pool contains a user-definable number of buffers determined by the `paxStatBuff` parameter that transfers file system metadata. Upon receiving metadata buffers, NASS traverses the backup file system or directory and returns metadata to the stat buffer pool. When a metadata buffer is available, a backup thread backs up one directory or file per thread, in sequential order. When a thread completes its portion of the backup, it waits for subsequent threads to complete their backup portions before starting a new one.

## Multithreaded restore process

The multithreaded restore process involves the NASA and NASW thread groups. You can define the number of restore threads through the `nRestore` parameter. Each restore thread is responsible for a single small file or part of a bigger file. When the backup software begins the restore process, the NASA thread activates the restore threads and waits for NASW to deliver data to the data buffer pool. The user-definable `ReadBuff` parameter determines the number of buffers between the NASA and NASW thread groups.

The tasks to configure NDMP backups on VNX are:

**CAUTION**

It is recommended to using the default values for most parameters except as otherwise noted in this document because these values optimize performance in most cases. Maximizing all parameter values will not always result in better performance, and could possibly result in Data Mover panic.

- ◆ [Configure Data Movers on page 46](#)
- ◆ [Set up the TLU on page 53](#)
- ◆ [Assign a username and a password to a Data Mover on page 56](#)
- ◆ [Set environment variables on page 58](#)

---

## Configure Data Movers

The tasks to configure Data Movers are:

1. [Configure the tape buffer size on page 46](#)
2. [Configure the read or write block size on page 47](#)
3. [Configure an NS series Data Mover on page 47](#)
4. [Configure Data Movers for international character sets on page 48](#)
5. [Override the autonegotiated NDMP version on page 49](#)
6. [Configure the Data Mover to increase the NDMP sessions \(Optional\) on page 50](#)
7. [Configure the NDMP port range on page 51](#)

---

## Configure the tape buffer size

The tape buffer size specifies the size of the buffer allocated for reading and writing to the tape. Most backup software vendors work with the VNX default buffer size of 128. [Tape drive buffer sizes on page 129](#) explains how to set the correct parameter value for the tape drive.

EMC NetWorker and Fujitsu-Siemens NetWorker, however, require different buffer sizes for different tape drive types. [EMC NetWorker on page 124](#) contains a partial list of tape buffer values used by NetWorker and Fujitsu-Siemens NetWorker.

Action
<p>To configure the tape buffer size, use this command syntax:</p> <pre>\$ server_param &lt;movername&gt; -facility NDMP -modify bufisz -value &lt;new_value&gt;</pre> <p>where:</p> <p>&lt;movername&gt; = name of the Data Mover</p> <p>&lt;new_value&gt; = value you want to set for the parameter</p> <p>Example:</p> <p>To set the bufisz parameter to 256, type:</p> <pre>\$ server_param server_2 -facility NDMP -modify bufisz -value 256</pre>

---

Note: Parameter and facility names are case-sensitive.

---

## Configure the read or write block size

The read or write block size parameter specifies the maximum allowed PAX buffer size for NDMP read or write. Most backup software vendors work with VNX default read or write block size of 64. However, the EMC Data Manager (EDM) feature requires a bigger block size for the backup or restore process to succeed. [Configure EMC Data Manager with NDMP on page 120](#) provides more details on using EDM.

Action
<p>To configure the read/write block size, use this command syntax:</p> <pre>\$ server_param &lt;movername&gt; -facility PAX -modify readWriteBlockSizeInKB -value &lt;new_value&gt;</pre> <p>where:</p> <p>&lt;movername&gt; = name of the Data Mover</p> <p>&lt;new_value&gt; = value you want to set for the parameter</p> <p>Example:</p> <p>To set the readWriteBlockSizeInKB parameter to 128, type:</p> <pre>\$ server_param server_2 -facility PAX -modify readWriteBlockSizeInKB -value 128</pre>

Note: Parameter and facility names are case-sensitive. The default value must be changed to 128 when using EDM for backup and restore operations.

## Configure an NS series Data Mover

From version 5.4 and later, you do not have to configure the Data Mover before backing up the data to a locally attached tape drive. The hardware autodetects and configures for arbitrated loop or switched fabric connections. Further, you do not have to specify the tape backup link speed. By default, the speed will be autonegotiated to the highest mutually acceptable link speed.

Follow this procedure if the autonegotiation fails and you need to configure the link speed manually.

Note: NS series require an MIA for device connection to the AUX-0 port. Your EMC Customer Support Representative can assist in installing the MIA.

Perform the following steps to configure NS series Data Mover:

1. To specify a tape backup link speed manually on an NS series Data Mover, use this command syntax:

```
$ server_param <movername> -facility fcTach -modify linx_speed_aux0
-value <new_value>
```

where:

<movername> = name of the Data Mover

<new\_value> = 0x1000 (to set tape backup link speed to 4 GB/s), 0x2000 (to accommodate a 2 GB Fibre Channel-Arbitrated Loop interface), 0x4000 (to accommodate an LC optical 1 GB interface) or 0x8000 (to detect the link speed from controller)

Example:

To set the link speed to accommodate a 2 GB Fibre Channel speed, type:

```
$ server_param server_2 -facility fcTach -modify linx_speed_aux0 -value 0x2000
```

---

Note: Parameter and facility names are case-sensitive.

---

- To restart the Data Mover for the parameter to take effect, use the command syntax:

```
$ server_cpu <movername> -reboot -monitor now
```

where:

<movername> = name of the Data Mover

Example:

To restart server\_2, type:

```
$ server_cpu server_2 -reboot -monitor now
```

---

## Configure Data Movers for international character sets

Use this procedure to configure the Data Mover for international character sets. [Implement international character support with NDMP on page 36](#) and *Using International Character Sets on VNX for File* provide more information on support and behavior of international character sets.

This section explains how to specify a dialect in VNX. You will need to specify a dialect if:

- Your backup software does not support Unicode, and a backup is done with Unicode enabled on VNX. The filename must then be converted.
- VNX is in internationalization mode and you are restoring a backup image of an ASCII-mode Data Mover where a non-Latin1 dialect was used.

---

Note: During a backup, if a file is found that the translation configuration file cannot translate a particular file, an entry is created in the `server_log` file. For example, if a file was created by using a character not appearing in the code page's character set, or if an NDMP dialect does not match the dialect used to create the file; then an entry is created in the server log. When restoring, you cannot perform a single-file restore on a file containing an invalid (`inode_<number>`) filename. To restore the file, you must restore the entire directory in which the file resides.

---

Perform the following steps to configure Data Movers for international character sets:

1. To determine the dialect you want to assign to the Data Mover, use these guidelines:
  - If Unicode was enabled during the backup and your backup software does not support Unicode, use the same dialect as the Data Mover client.
  - If you are restoring a backup image of an ASCII-mode Data Mover where a non-Latin1 dialect was used, and VNX is in internationalization mode, specify the dialect used on the ASCII-mode Data Mover.
2. To set the dialect, use the command syntax:

```
$ server_param <movename> -facility NDMP -modify dialect
-value <new_value>
```

where:

<movename> = name of the Data Mover

<new\_value> = value that matches the dialect on the Data Mover client

Example:

To set the dialect to big5, type:

```
$ server_param server_2 -facility NDMP -modify dialect -value big5
```

Output:

```
server_2 : done
```

---

Note: Parameter and facility names are case-sensitive.

---

## Override the autonegotiated NDMP version

Complete this procedure if you want to force VNX to use an earlier version of NDMP, such as version 3.

By default, some servers and NDMP devices autonegotiate to use the latest NDMP version supported by the Data Mover and the NDMP backup software. It is recommended to use this default setting. If necessary, you can override the process by specifying the latest NDMP version. Overriding the NDMP version can help you isolate a problem by determining

whether it occurs with different NDMP autonegotiated versions. Autonegotiation between VNX and the NDMP client determines the highest NDMP version used.

Note: Parameter and facility names are case-sensitive. The `maxProtocolVersion` parameter setting overrides the autonegotiation.

Action
<p>To override the autonegotiated NDMP version, use this command syntax:</p> <pre>\$ server_param &lt;movername&gt; -facility NDMP -modify maxProtocolVersion -value &lt;new_value&gt;</pre> <p>where:</p> <p>&lt;movername&gt; = name of the Data Mover</p> <p>&lt;new_value&gt; = value you want to set for the parameter</p> <p>Example:</p> <p>To set the NDMP version to 3, type:</p> <pre>\$ server_param server_2 -facility NDMP -modify maxProtocolVersion -value 3</pre>
Output
<pre>server_2 : done</pre>

## Configure the Data Mover to increase the NDMP sessions (Optional)

VNX supports a maximum of eight NDMP sessions for each NDMP-Host Data Mover. By default, up to four NDMP sessions are performed at a time. You can configure the Data Mover to change the value of the NDMP sessions from four up to eight.

Use the following procedures to:

- ◆ [View the value of concurrent NDMP sessions on page 50](#)
- ◆ [Configure the NDMP concurrent sessions on page 51](#)

### View the value of concurrent NDMP sessions

Action
<p>To view the value of concurrent NDMP sessions, use this command syntax:</p> <pre>\$ server_param {ALL  &lt;mover&gt;} -facility NDMP -info concurrentDataStreams</pre> <p>To view the value of concurrent NDMP sessions, type:</p> <pre>\$ server_param server_2 -facility NDMP -info concurrentDataStreams</pre>

## Output

```
server_2:
name = concurrentDataStreams
facility_name = NDMP
default_value = 4
current_value = 4
configured_value =
user_action = reboot DataMover
change_effective = reboot DataMover
range = (1,8)
description = number of concurrent data streams
```

### Configure the NDMP concurrent sessions

## Action

To change the value of concurrent sessions, use this command syntax:

```
$ server_param {ALL|<movername>} -facility NDMP -modify concurrentDataStreams
-value <number_of_sessions>
```

where:

<movername> = name of the Data Mover

<number\_of\_sessions> = number of concurrent NDMP sessions to be performed

Example:

To change the value of the concurrent NDMP sessions to eight, type:

```
$ server_param server_2 -facility NDMP -modify concurrentDataStreams -value 8
```

Note: If the Data Mover has less than 8 GB memory, you cannot set the value of the concurrentDataStreams parameter to more than four. The server\_param command will fail with the error message, "8 is not in range (1, 4)".

## Output

```
server_2: You must reboot server_2 for concurrentDataStreams changes to
take effect.
```

### Configure the NDMP port range

You can set the NDMP port range in order to limit the NDMP data connection listening port, to support firewall configurations. To specify the port range use the portRange parameter. It is recommended to set the NDMP port range by using dynamic or private ports (49152-65535) of IANA. You can set the minimum and maximum port range as per your requirement. The required minimum value of the port width is 32, however it is recommended to set the width to at least 100. Setting the port range does not imply that these ports are reserved for NDMP connection. When the port range is set, NDMP selects a random port number from the specified port range as the data connection listening port.

The port range feature does not support NAT. It uses the existing server\_param management interface and is independent of the DMA. Configuring the NDMP port range allows the Data Mover to use a limited range of TCP ports that correspond to the ports for which the firewall allows inbound connections.

**Note:** You could need to configure the DMA to allow specific ports for outbound connections.

Use the following procedures to:

- ◆ [View the port range on page 52](#)
- ◆ [Configure the port range on page 52](#)

### View the port range

Action
<p>To view the value of the NDMP port range, use this command syntax:</p> <pre>\$ server_param {ALL &lt;movername&gt;} -facility NDMP -info portRange</pre> <p>where:</p> <p>&lt;movername&gt; = name of the Data Mover</p> <p>Example:</p> <p>To view the value of the NDMP port range, type:</p> <pre>\$ server_param server_2 -facility NDMP -info portRange</pre>
Output
<pre>server_2 : name = portRange facility_name = NDMP default_value = 1024-65535 current_value = 1024-65535 configured_value = user_action = none change_effective = immediate range = 1024-65535 description = Port range for NDMP data connection listening</pre>

### Configure the port range

Action
<p>To set the value of the NDMP port range, use this command syntax:</p> <pre>\$ server_param {ALL &lt;movername&gt;} -facility NDMP -modify portRange -value 50000-50100</pre> <p>where:</p> <p>&lt;movername&gt; = name of the Data Mover</p>

Action
<p>Example:</p> <p>To set the value of the NDMP port range, type:</p> <pre>\$ server_param server_2 -facility NDMP -modify portRange -value 50000-50100</pre>
Output
server_2 : done

Note: You can also use Unisphere to modify and display the NDMP portRange parameter. In Unisphere, select Settings and click Data Mover Parameters. See the Unisphere help for more information.

## Set up the TLU

Setting up the TLU includes the steps for connecting a physical TLU and retrieving and recording physical device names. *Configuring NDMP Backups to Disk on VNX* provides information on configuring virtual tape library emulation software and disk storage on a Data Mover.

You need the device names for the robot and drives when configuring the backup software. VNX addresses a TLU device component as follows:

```
<SCSI_controller> <SCSI_ID> <SCSI_LUN>
```

where:

```
<SCSI_controller> = chain number of the controller
```

```
<SCSI_ID> = SCSI ID (target) of the controller
```

```
<SCSI_LUN> = logical unit number (LUN) of the controller
```

Note: For backups with VNX, an MIA adapts the Fibre Channel AUX-0 port from an HSSDC copper interface to an LC optical interface. For backups with VNX series, an SFP adapter is used. Instructions on how to install an MIA in VNX, or an SFP in VNX series, are documented in individual setup guides provided with each system.

Perform the following steps to set up the TLU:

1. To halt each Data Mover to be connected to the TLU and confirm it has halted from the Control Station, use this command syntax:

```
$ server_cpu <movername> -halt -monitor now
```

where:

```
<movername> = name of the Data Mover
```

Example:

To halt the Data Mover running on server\_2, type:

```
$ server_cpu server_2 -halt -monitor now
```

2. Type `/nas/sbin/getreason` and ensure that the status is powered off.
3. Cable each Data Mover to the TLU. [Data Mover-to-TLU cabling examples on page 35](#) provides more information.
4. Turn on the TLU and verify that it is online.
5. To restart each Data Mover connected to the TLU and confirm it has restarted, use this command syntax:

```
$ server_cpu <movername> -reboot -monitor now
```

where:

`<movername>` = name of the Data Mover

Example:

To restart `server_2`, type:

```
$ server_cpu server_2 -reboot -monitor now
```

Output:

```
server_2: reboot in progress 0.0.0.0.0.1.1.3.3.3.3.3.3.3.4. done
```

6. To verify that the Data Mover can recognize its TLU device, use this command syntax:

```
$ server_devconfig <movername> -probe -scsi -nondisks
```

where:

`<movername>` = name of the Data Mover

---

Note: The `server_devconfig` command discovers only physical devices. It does not discover virtual devices.

---

Example:

To verify that `server_2` can recognize its TLU devices, type:

```
$ server_devconfig server_2 -probe -scsi -nondisks
```

7. To save the TLU devices of the Data Mover to the VNX database, use this command syntax:

```
$ server_devconfig <movername> -create -scsi -nondisks
```

where:

`<movername>` = name of the Data Mover

 In VNX for block environment, before you run the `server_devconfig -create` command, verify that all paths to the Data Mover are active and no LUNs are trespassed. Running this command while paths are inactive causes errors in the Data Mover configuration file.

Example:

To save the device information to the database, type:

```
$ server_devconfig server_2 -create -scsi -nondisks
```

8. To list the device addresses, use this command syntax:

```
$ server_devconfig <movername> -list -scsi -nondisks
```

where:

<movername> = name of the Data Mover

Example:

To list the devices for server\_2, type:

```
$ server_devconfig server_2 -list -scsi -nondisks
```

Output:

```
server_2 :
Scsi device table
name addr type info
jbox1 c1t010 jbox ATL P1000 62200501.21
tape2 c1t410 tape QUANTUM DLT7000 245Fq_
tape3 c1t510 tape QUANTUM DLT7000 245Fq_
```

9. Record the device name information as shown in [Table 3 on page 56](#). It shows the type of configuration information to record. You will need the device names when you configure your backup software.
10. Perform this procedure for each Data Mover attached to the TLU.

## Configure stand-alone tape drives

When configuring stand-alone tape drives, it is recommended to prefix the VNX device name with `c` in your backup software. This ensures that tape compression is used during a backup. For example, to use tape compression for the device `C1T0L0`, type `cC1T0L0` as the device name. To turn off compression, prefix the device name with `u`. When no prefix is specified, the default compression setting for the tape drive is used.

**Table 3. Sample device name information**

Data Mover	TLU SCSI port	Resulting device name	Device component
server_x	chain 1, target 0, LUN 0	C1T0L0	Robot
server_y	chain 1, target 4, LUN 0	C1T4L0	Tape Drive 1
server_z	chain 1, target 5, LUN 0	C1T5L0	Tape Drive 2

## Configure VTLUs

To configure VNX for NDMP backups to disk, configure a VTLU, and then associate storage with the VTLU. *Configuring NDMP Backups to Disk on VNX* contains information about configuring VTLUs. VTLU backups require the same VNX configuration settings as NDMP backups to tape. Depending on your backup software vendor, you will need to complete some or all of these tasks that are described in these sections:

- ◆ [Configure the Data Mover on page 141](#)
- ◆ [Assign a username and a password to a Data Mover on page 56](#)
- ◆ [Set environment variables on page 58](#)

## Assign a username and a password to a Data Mover

NDMP configuration for the backup software and VNX requires setting a trusted username and password for each NDMP-Host Data Mover. The methods to set the username and password are:

- ◆ [With NIS on page 57](#)
- ◆ [Without NIS on page 57](#)

---

## With NIS

For Network Information Service (NIS) installations, the username and password must match the username and password in the NIS database.

---

**Note:** The same username and password should be typed when you configure the backup software.

---

NIS must be enabled on every NDMP-Host Data Mover.

---

**Note:** Use the text password method only to create an NDMP account in the NIS environment. Also, ensure that the NDMP.md5 parameter is set to 0 (zero) on all Data Movers in this environment. The *Parameters Guide for VNX for File* provides information about the NDMP.md5 parameter.

---

---

## Without NIS

Perform the following steps to assign a username and password to a Data Mover without NIS:

1. To assign a user account name and password to one or more Data Movers, log in to the Control Station as nasadmin and switch user to root by typing:

```
$ su
```

2. Type the root password when prompted.
3. To create an account, use the appropriate command syntax, as follows:

Text method:

```
# /nas/sbin/server_user <movername> -add -password <username>
```

---

**Note:** Before using the text method, change the value of the NDMP.md5 parameter to 0.

---

MD5 password encryption method:

```
# /nas/sbin/server_user <movername> -add -md5 -password <username>
```

where:

*<movername>* = name of the Data Mover to which you want to assign a user account and password

*<username>* = name of the user account you want to assign to the Data Mover

---

**Note:** For security reasons, it is recommended that you use the MD5 password encryption method.

---

**Output:**

```

Creating new user user_name
User ID: 1000
Group ID: 1000
Home directory:
Changing password for user user_name
New passwd:
Retype new passwd:
server_2 : done

```

---

**Note:** In the output, the two mandatory fields, User ID (UID) and Group ID (GID), are integers. VNX uses UNIX-style UIDs and GIDs to record the ownership of files and directories. The UID of the root user is 0. The password you assign to the Data Mover can contain between six and eight characters.

---

**Examples:**

To create an account by using the text method, type:

```
# /nas/sbin/server_user server_2 -add -password user_name
```

To create an account by using the MD5 encryption method, type:

```
# /nas/sbin/server_user server_2 -add -md5 -password user_name
```

4. Repeat steps 1, 2, and 3 for each NDMP-Host Data Mover.

---

## Set environment variables

[Table 4 on page 58](#) lists environment variables supported by VNX. Refer the backup vendor documentation for more information about environment variable requirements, as backup vendors use and implement variables differently.

**Table 4. Environment variables**

Variable	Possible values	NDMP spec default value	Description
BASE_DATE	Obtained from the NDMP client for the previous backup operation or set to 0 (zero) for a full backup.	N/A	Incremental count and date/time of previous backup operation.  Note: This variable works in conjunction with DUMP_DATE.  When BASE_DATE is specified, LEVEL is ignored. <a href="#">Backup levels with VNX and NDMP on page 24</a> offers more details.
DIRECT	y/n	n	Improves restore results. Must be enabled to invoke DAR functionality.

Table 4. Environment variables (continued)

Variable	Possible values	NDMP spec default value	Description
DUMP_DATE	Obtained from the NDMP server for the current backup operation only if BASE_DATE is specified by the NDMP client as part of the environment.	N/A	Incremental count and date/time of current backup operation.  Note: This variable works in conjunction with BASE_DATE.  <a href="#">Backup levels with VNX and NDMP on page 24</a> shows how to use DUMP_DATE in a backup session.
EMC_EDIR[01-50]	<path name> as /fs/directory	blank	Specifies the directory to exclude from the NDMP backup session. <a href="#">Exclude directories or files from backup by using filtering on page 86</a> provides details on using this directory filter.  By default, the maximum number of directory filters is five. You can increase this to a maximum of 50 by using the filter.numDirFilter parameter. <a href="#">Modify parameters on page 69</a> provides more details.
EMC_EFILE[01-50]	<filename> or <file type>	blank	Specifies the file, or a type of file, to exclude from the NDMP backup session. <a href="#">Exclude directories or files from backup by using filtering on page 86</a> shows how to use this file filter. By default, the maximum number of file filters is five. You can increase this to a maximum of 50 by using the filter.numFileFilter parameter. <a href="#">Modify parameters on page 69</a> provides more details.
EMC_OFFLINE_DATA	y/n	n	By default, VNX backs up the attributes associated with migrated files.  Y specifies that VNX backup migrated data as well as attributes.  This variable applies when using NDMP to back up VNX FileMover-enabled file system.  <a href="#">Back up a FileMover file system with NDMP on page 74</a> and <a href="#">Using VNX FileMover</a> contain more details on VNX FileMover.
FILESYSTEM	<pathname>	N/A	The path to be backed up.

Table 4. Environment variables (continued)

Variable	Possible values	NDMP spec default value	Description
HIST	y/n	n	Determines if a file history is created. Set HIST= y before you perform a backup to be able to perform a direct-access restore operation later.
LEVEL	0-10	0	Dump level. <a href="#">Backup levels with VNX and NDMP on page 24</a> explains how to set backup levels.
OPTION	NT LK MI/MD/MM	NT for tar and dump	Saves NT attributes. Follows symbolic links. Sets collision policy for localization during restore.
OVERWRITE	y/n	y	Determines whether a file should be restored or skipped, if a file of the same name exists on the destination location.  The OVERWRITE variable can be set using your backup application. If the value of this variable is set at the time of backup, it will be applicable to all the restores performed from that backup. This value can be changed, at the time of restore, if it is allowed by the backup application.
PREFIX	<pathname>	N/A	PREFIX can be used in place of FILESYSTEM for backward compatibility.
RECURSIVE	y/n	y	Recursively restores any given directory.  In version 5.5 or later, recursive must be enabled to affect expected restore functionality.
SNAPSURE	y/n	n	Determines if a checkpoint created using VNX SnapSure is automatically created, mounted, used for the backup, and deleted when the backup completes. This must be set to y for these automated activities to occur. Once set to y, the automation occurs every time you run that particular job.  <a href="#">Back up a FileMover file system with NDMP on page 74</a> explains how to use this feature.

Table 4. Environment variables (continued)

Variable	Possible values	NDMP spec default value	Description
TYPE	tar or dump or vbb	N/A	The backup type.  Note: Dump format does not cross file system boundaries.
VLC	y/n	n	Specifies an NDMP Volume-Level Copy to tape. You must use a read-only file system for a volume-level copy. The VLC option can be used for the first fs_copy when configuring EMC VNX Replicator.  Note: This feature has not been qualified with backup software vendors.
VBB	y/n	n	Specifies backup type to VBB.
RETAIN_ETIME	Y/N	N	By default, the RETAIN_ETIME is set to "N". VNX restores the file and apply the etime to mtime.  When the RETAIN_ETIME is set to "Y", the etime is set as the last access time approximately. VNX restores the file and applies the retained etime to the file.  <a href="#">NDMP last access time on page 42</a> provides more information.

The tasks to manage NDMP backups are:

- ◆ [Manage backup parameters and statistics on page 64](#)
- ◆ [Back up a VDM file system with NDMP on page 74](#)
- ◆ [Back up a FileMover file system with NDMP on page 74](#)
- ◆ [Restore a FileMover file system on page 75](#)
- ◆ [Back up a file system with NDMP by using an integrated SnapSure checkpoint on page 75](#)
- ◆ [Perform backup and restore with NVB on page 75](#)
- ◆ [Perform NVB restores on page 77](#)
- ◆ [Exclude directories or files from backup by using filtering on page 86](#)
- ◆ [Perform tape silvering on page 88](#)

## Manage backup parameters and statistics

The tasks to manage backup and restore parameters and view backup and restore statistics are:

- ◆ [View backup parameters on page 64](#)
- ◆ [View a specific parameter on page 66](#)
- ◆ [View all parameters on page 67](#)
- ◆ [Modify parameters on page 69](#)
- ◆ [View backup statistics on page 70](#)
- ◆ [Reset backup statistics on page 73](#)

### View backup parameters

Action				
To view backup parameters and their values, use this command syntax:				
<code>\$ server_param &lt;movename&gt; -facility PAX -list</code>				
where:				
<code>&lt;movename&gt;</code> = name of the Data Mover				
Example:				
To view a list of PAX parameters on server_2, type:				
<code>\$ server_param server_2 -facility PAX -list</code>				
Output				
param_name	facility	default	current	configured
dump	PAX	0	0	
allowVLCRestoreToUFS	PAX	0	0	
checkUtf8Filenames	PAX	1	1	
paxStatBuff	PAX	128	128	
readWriteBlockSizeInKB	PAX	64	64	
filter.numFileFilter	PAX	5	5	
filter.numDirFilter	PAX	5	5	
noFileStreams	PAX	0	0	
scanOnRestore	PAX	1	1	
filter.caseSensitive	PAX	1	1	
nRestore	PAX	16	16	
writeToArch	PAX	1	1	
writeToTape	PAX	1	1	

**Note**

where:

param\_name = name of the parameter

facility = facility to which the parameter belongs

default = default value for the parameter

current = value set on the Data Mover

configured = value set that has not taken effect yet because some user action, such as a Data Mover restart, is required.

---

**Note:** The configured and current values can differ when you use the `server_param` command to configure the value of a parameter that is different from the default value. Furthermore, changing the parameter requires user action such as a Data Mover restart to take effect. Parameter and facility names are case-sensitive.

---

## View a specific parameter

### Action

To view detailed information on a specific parameter, use this command syntax:

```
$ server_param {<movername>|ALL} -facility <facility_name> -info
<param_name>
```

where:

<movername> = name of the Data Mover (or keyword ALL for all Data Movers)

<facility\_name> = name of the facility to which the parameter belongs

<param\_name> = name of the parameter you want to view

Example:

To view detailed information on the paxStatBuff parameter on server\_2, type:

```
$ server_param server_2 -facility PAX -info paxStatBuff
```

Note: Parameter and facility names are case-sensitive.

### Output

```
name = paxStatBuff
facility_name = PAX
default_value = 128
current_value = 64
configured_value = 64
user_action = none
change_effective = immediate
range = (1,512)
description = Number of buffers in stat queue per backup session
```

### Note

The output in this example shows the paxStatBuff parameter value has been increased from the default value to 128.

Output definitions:

facility\_name = facility to which the parameter belongs

default\_value = value set as the default

current\_value = value set on the Data Mover

configured\_value = value configured with the server\_param command

user\_action = action necessary for the parameter change to take effect

change\_effective = when the parameter change takes effect

range = range of possible values

## Note

description = description of the parameter (*Parameters Guide for VNX for File* provides more information.)

## View all parameters

Action
<p>To view all parameters for a particular Data Mover, use this command syntax:</p> <pre>\$ server_param &lt;movername&gt; -facility &lt;facility_name&gt; -info -all</pre> <p>where:</p> <p>&lt;movername&gt; = name of the Data Mover</p> <p>&lt;facility_name&gt; = name of the facility to which the parameter belongs</p> <p>Example:</p> <p>To view all PAX parameters on server_2, type:</p> <pre>\$ server_param server_2 -facility PAX -info -all</pre>
Output
<pre>name = paxStatBuff facility_name = PAX default_value = 128 current_value = 128 configured_value = user_action = none change_effective = immediate range = (1,512) description = Number of buffers in stat queue per backup session  name = nRestore facility_name = PAX default_value = 8 current_value = 8 configured_value = user_action = none change_effective = immediate range = (1,16) description = Number of worker threads per restore session  name = readWriteBlockSizeInKB facility_name = PAX default_value = 64 current_value = 64 configured_value = user_action = reboot DataMover change_effective = reboot DataMover range = (64,256) description = Maximum allowed PAX buffer size for NDMP read/write in kilobytes</pre>

---

Note: Consult the example presented in [View a specific parameter on page 66](#) to view detailed information on a specific parameter, for an explanation of the categories displayed in this output.

---

## Modify parameters

**CAUTION**

- ◆ Parameters allow you to increase the number of threads and data blocks used during the backup and restore processes. However, more threads and data blocks use more of the Data Mover memory normally dedicated to the backup and restore processes. Therefore, using more threads and data blocks can negatively impact other processes running on the Data Mover.
- ◆ Parameter changes made while backups are running on a Data Mover take effect only after any backups on the Data Mover complete.

Action
<p>To modify a parameter, use this command syntax:</p> <pre>\$ server_param {&lt;movername&gt; ALL} -facility &lt;facility_name&gt; -modify &lt;param_name&gt; -value &lt;new_value&gt;</pre> <p>where:</p> <p>&lt;movername&gt; = name of the Data Mover (or keyword ALL for all Data Movers)</p> <p>&lt;facility_name&gt; = name of the facility to which the parameter belongs</p> <p>&lt;param_name&gt; = name of the parameter</p> <p>&lt;new_value&gt; = new value you want to set for the parameter. Numeric values can be given as either a decimal value or in hexadecimal format (0x followed by one to eight hexadecimal characters). To specify a null string, type double quotation marks (" ").</p> <p>Note: Parameter and facility names are case-sensitive.</p> <p>Example:</p> <p>To set the paxStatBuff parameter to 128, type:</p> <pre>\$ server_param server_2 -facility PAX -modify paxStatBuff -value 128</pre>
Output
<pre>server_2 : done</pre>

## View backup statistics

The procedure to view backup statistics describes how to use the `server_pax` command to view statistics related to your file system data and backup performance.

Note: When you restore data to a location different from its original location, the new path for the data does not appear in the backup statistics. The `server_pax` command only supports viewing PAX-based backup statistics, not statistics associated with NVBs.

Action
<p>To view statistics on a backup session in progress, use this command syntax:</p> <pre>\$ <b>server_pax</b> &lt;movername&gt; <b>-stats -verbose</b></pre> <p>where:</p> <p>&lt;movername&gt; = name of the Data Mover</p> <p>Example:</p> <p>To view statistics for a backup running on server_2, type:</p> <pre>\$ <b>server_pax server_2 -stats -verbose</b></pre>

The output is grouped by thread group, which performs various functions within the multithreaded backup and restore process. [Multithreaded backup and restore design on page 42](#) provides more information.

## Output

```

***** SUMMARY PAX STATS *****
---- NASS STATS ----
** nass thid 0 **
Total file processed: 16
throughput: 2 files/sec
Total nass wait nasa count: 13

```

## Note

When you specify verbose mode, information on file size distribution is included in the output.

where:

NASS STATS = thread responsible for traversing the file system and providing metadata for each directory and/or file

Total file processed = total number of files and/or directories for which metadata was processed

Total NASS wait NASA count = number of times NASS waited for NASA

Total NASS wait NASA time = amount of time NASS waited for NASA

Total time since last reset = time since the last reset; a reset occurs automatically after a backup completes

fts\_build time = time spent building the file system or directory tree

getstatpool = if the value is consistently 0, then NASA could be slowing down the backup

putstatpool = if the value is consistently 0, then NASS could be slowing down the backup

NASA STATS = thread responsible for writing file header information, reading file data, and writing to the buffer

Backup root directory = directory being backed up

Total bytes processed = bytes backed up since last reset or start of current backup

Total file processed = number of files backed up since start or reset of current backup

Throughput = how fast NASA processed data

Average file size = average size of file for current backup

Total nasa wait nass count time = number of times NASA waited for NASS

Total nasa wait nass time = amount of time NASA waited for NASS

Total time since last reset = amount of time since the backup statistics were reset; a reset occurs automatically after a backup completes

Tape device name = target device for the backup data

File size statistics = statistics on the size of files backed up since the start or reset of the current backup

NASW STATS = thread responsible for getting data from the buffer pool, writing it to tape, or sending it to a remote Data Mover

Session total time = total time of current session

Session idle time = idle time for current session

Note
KB transferred = total KB transferred
Average transfer rate = per-second and per-hour transfer rate for current session's data
Average burst transfer = burst transfer rate in MB/s and GB/h
Write block counters (List/Direct) = scatter/gather write count
_Point-in-time_ (over the last 10 seconds) = information on data processed during a 10 second point in time
Rate = transfer rate in MB/s
Burst = burst transfer rate in MB/s
Idle = amount of time NASW was idle in msec
Get pool = number of buffers in get pool; if the value is consistently 0, then NASA and NASS could be slowing down the backup
Put pool = number of buffers in put pool; if the value is consistently 0, then the tape could be slowing down the backup
Compression rate retrieved = compression rate
ReadC = read compression rate at the tape device
WriteC = write compression rate at the tape device
Read = amount of data read in KB
Written = amount of data written in KB

## Reset backup statistics

Statistics are compiled for each backup session and automatically reset when a backup completes.

Action
<p>To reset statistics for a backup session in progress, use this command syntax:</p> <pre>\$ server_pax &lt;movername&gt; -reset</pre> <p>where:</p> <p>&lt;movername&gt; = name of the Data Mover</p> <p>Example:</p> <p>To reset the statistics for a backup running on server_2, type:</p> <pre>\$ server_pax server_2 -reset</pre>
Output
<pre>server_2 : done</pre>

## Back up a VDM file system with NDMP

This procedure explains only the NDMP-specific guidelines for Virtual Data Mover (VDM). *Configuring Virtual Data Movers on VNX* provides more information on VDM.

A VDM enables you to administratively separate CIFS servers and their associated resources, like file systems, into virtual containers. These virtual containers allow administrative separation between groups of CIFS servers, enable replication of CIFS environments, and allow the movement of CIFS servers from Data Mover to Data Mover. In a CIFS environment, when you use NDMP to back up a VDM configured file system, you must specify the full mount path of the file system.

Perform the following steps to backup a VDM file system with NDMP:

1. To retrieve the full mount path of a file system, use this command syntax:

```
$ server_mount <movername> | grep <fs_name>
```

where:

<movername> = name of the Data Mover

<fs\_name> = name of the file system for which you want the full path

Example:

To retrieve the full mount path of file system ufs1, type:

```
$ server_mount server_2 | grep ufs1
```

Output:

```
ufs1 on /root_vdm_1/ufs1 udfs,perm,rw
```

Note: /root\_vdm\_1, in this example, indicates that the file system is a VDM-configured file system. To back up this file system by using NDMP, type /root\_vdm\_1/ufs1 as the full path in the backup software.

2. In the NDMP backup software, type the pathname revealed in step 1. For example:

```
/root_vdm_1/ufs1
```

Note: Your backup software vendor's documentation provides more information on specifying file system pathnames in your NDMP backup software.

## Back up a FileMover file system with NDMP

To include the file content on secondary storage, set this NDMP environment variable in your backup software:

```
EMC_OFFLINE_DATA=y
```

---

Note: When you use the default setting EMC\_OFFLINE\_DATA=n, the content on secondary storage is not backed up.

---

---

## Restore a FileMover file system

When you restore a FileMover file system that includes content from the primary and secondary storage systems, the behavior is the same as with any other file system restore: the entire file system is restored as online files. To restore a file system as online content, the file system must be backed up with the environment variable EMC\_OFFLINE\_DATA=y set in the backup software.

When an NDMP backup is performed with the environment variable EMC\_OFFLINE\_DATA=n, which is the default configuration, only the primary storage content is backed up. When you restore such a file system, the stub files are restored, and they continue to serve as pointers to access the file content on secondary storage. The file content remains on secondary storage as long as its associated policy dictates. *Using VNX FileMover* provides more information on the FileMover feature.

---

## Back up a file system with NDMP by using an integrated SnapSure checkpoint

To integrate a checkpoint into the NDMP backup process and automate the checkpoint creation, management, and deletion tasks upon initiation of backups, set this NDMP environment variable in your backup software:

**SNAPSURE=y**

---

Note:

- ◆ If you use the default setting SNAPSURE=n in the backup software, no automated checkpoint activity occurs.
  - ◆ If the backup software does not support the SNAPSURE=y environmental variable, you can set the parameter NDMP.snapsure in the Data Mover to use VNX SnapSure for backup. The default parameter value 0 should be changed to 1.
- 

---

## Perform backup and restore with NVB

[Backup/restore with NVB on page 29](#) provides information about backing up and restoring volumes with NVB:

- ◆ [Specify NVB in backup vendor software on page 76](#) provides information about specifying NVB in vendor backup software.

- ◆ [Perform NVB restores on page 77](#) provides information about performing NVB restores.

## Specify NVB in backup vendor software

Some backup software vendors support the use of backup types, others support the use of environmental variables, and some vendors support both. Therefore, the action required to initiate a VBB depends on your backup software vendor. The EMC E-Lab Interoperability Navigator provides a current list of EMC-qualified backup software vendors for NVB and their supported implementation methods.

This section shows an example of implementing NVB by specifying VBB as the backup type and VBB as an environmental variable in NetWorker and Symantec NetBackup. Your backup vendor documentation provides instructions on implementing backup types and environmental variables.

**Note:** Always ensure that the HIST=y and UPDATE=y environmental variables are set to create the index required for future direct-access restore operations. Do not use file and directory filters with NVB. They will have no effect.

### Specify NVB in EMC NetWorker

Action
To set the backup type, in the Client Properties window, at the <b>Application information</b> field, type:  <code>nsrndmp_save -Type vbb</code>
<b>Note:</b> In the NetWorker software, the backup type, VBB, must be typed in lowercase. Otherwise the backup immediately fails.
Or use this environmental variable: VBB=y

### Specify NVB in Symantec NetBackup

Action
To set the backup type, type:  <code>SET type=vbb</code>
Or use this environmental variable:  <code>SET VBB=y</code>

## Perform NVB restores

The types of restore that NVB supports are:

- ◆ Full destructive restore
- ◆ File-level restore

[Perform full destructive restore on page 77](#) and [File-level restore on page 85](#) provide more information.

### Perform full destructive restore

When performing a full destructive restore, the NVB feature requires the target file system be of equal size or greater than the file system backed up.

When you use the backup image created by using NVB to perform a full destructive restore, the restore occurs at the volume level. Large sequential writes are issued to the volume as data blocks are read from tape and written directly to the specified volume. All existing data on the target file system is destroyed. This type of restore ensures the best possible data block write performance.

**Note:** [Perform a full destructive restore of a VDM file system on page 85](#) describes the procedure to do a full destructive restore of a VDM file system.

Perform the following steps for a full destructive restore:

1. To complete a full NVB of a PFS by using the NVB backup mechanism in the backup-vendor software, type the following. In this example, the PFS is ufs1:

```
$ nas_fs -s ufs1
```

Output:

```
total = 73855 avail = 69133 used = 4721 ( 6%) (sizes in MB)
(blockcount = 153600000)
volume: total = 75000 (sizes in MB) (blockcount = 153600000)
```

2. To use Automatic Volume Management (AVM) in order to create the file system needed for the full destructive restore, type this command to get the pool information of the PFS, which is needed in the process:

```
$ nas_fs -i ufs1
```

Output:

```

id = 1150
name = ufs1
acl = 0
in_use = True
type = udfs
worm = off
volume = v1772
pool = clar_r5_performance
member_of = root_avm_fs_group_3
rw_servers= server_2
ro_servers=
rw_vdms =
ro_vdms =
auto_ext = no,virtual_provision=no
stor_devs = APM00043306037-000C,APM00043306037-
000F,APM00043306037-0008,APM00043
306037-000B
disks = d19,d11,d17,d9
disk=d19 stor_dev=APM00043306037-000C addr=c16t117
server=server_2
disk=d19 stor_dev=APM00043306037-000C addr=c32t117
server=server_2
disk=d19 stor_dev=APM00043306037-000C addr=c0t117
server=server_2

server=server_2
disk=d11 stor_dev=APM00043306037-000F addr=c0t1110
server=server_2
disk=d11 stor_dev=APM00043306037-000F addr=c48t1110
server=server_2
disk=d11 stor_dev=APM00043306037-000F addr=c16t1110
server=server_2
disk=d11 stor_dev=APM00043306037-000F addr=c32t1110
server=server_2
disk=d17 stor_dev=APM00043306037-0008 addr=c16t113
server=server_2
disk=d17 stor_dev=APM00043306037-0008 addr=c32t113
server=server_2
disk=d17 stor_dev=APM00043306037-0008 addr=c0t113
server=server_2
disk=d17 stor_dev=APM00043306037-0008 addr=c48t113
server=server_2
disk=d9 stor_dev=APM00043306037-000B addr=c0t116
server=server_2
disk=d9 stor_dev=APM00043306037-000B addr=c48t116
server=server_2
disk=d9 stor_dev=APM00043306037-000B addr=c16t116
server=server_2
disk=d9 stor_dev=APM00043306037-000B addr=c32t116
server=server_2

```

---

Note: In this output example, the pool is clar\_r5\_performance.

---

3. To create a raw file system (rawfs) to be used for the NVB full destructive restore (FDR), type:

```
$ nas_fs -name newufs1 -type rawfs -create samesize=ufs1 pool= clar_r5_performance
```

---

**Note:** The raw file system should be the same size as the PFS. The easiest method to ensure equivalency is to use the `samesize` option of the `nas_fs` command. If you do not use the `samesize` option, ensure that the rawfs is at least the same size as the PFS.

---

**Output:**

```
id = 1151
name = newufs1
acl = 0
in_use = False
type = rawfs
worm = off
volume = v1775
pool = clar_r5_performance
member_of = root_avm_fs_group_3
rw_servers=
ro_servers=
rw_vdms =
ro_vdms =
auto_ext = no,virtual_provision=no
stor_devs = APM00043306037-000E,APM00043306037-
000D,APM00043306037-000A,APM00043
306037-0009
disks = d20,d10,d18,d8
```

- To create the mount point for the raw file system, type:

```
$ server_mountpoint server_2 -c /newufs1
```

**Output:**

```
server_2 : done
```

- To mount the raw file system, type:

```
$ server_mount server_2 newufs1 /newufs1
```

**Output:**

```
server_2 : done
```

---

**Note:** When you list the file system, it appears as unmounted, as shown below. This is expected behavior.

---

```
$ server_mount server_2
```

**Output:**

```
server_2 :
root_fs_common on /.etc_common uxfs,perm,ro
ufs1 on /ufs1 uxfs,perm,rw
newufs1 on /newufs1 rawfs,perm,rw,<unmounted>
```

- To record the volume ID of the raw file system, type:

```
$ nas_fs -i newufs1
```

**Output:**

```
id = 1151
name = newufs1
acl = 0
in_use = False
type = rawfs
worm = off
volume = v1775
pool = clar_r5_performance
member_of = root_avm_fs_group_3
rw_servers=
ro_servers=
rw_vdms =
ro_vdms =
auto_ext = no,virtual_provision=no
stor_devs = APM00043306037-000E,APM00043306037-
00D,APM00043306037-000A,APM000430
306037-0009
disks = d20,d10,d18,d8
```

The volume ID in this output example is v1775. This ID without the leading "v" is required for the restore.

---

**Note:** The next step depends on the backup software you are using. For NetWorker, perform steps 7 through 9. For Symantec NetBackup, perform steps 10 through 12. After completing the required step, proceed to step 13.

---

#### 7. NetWorker procedure:

If you are performing a full destructive restore by using NetWorker software, perform steps 7 through 9.

In UNIX:

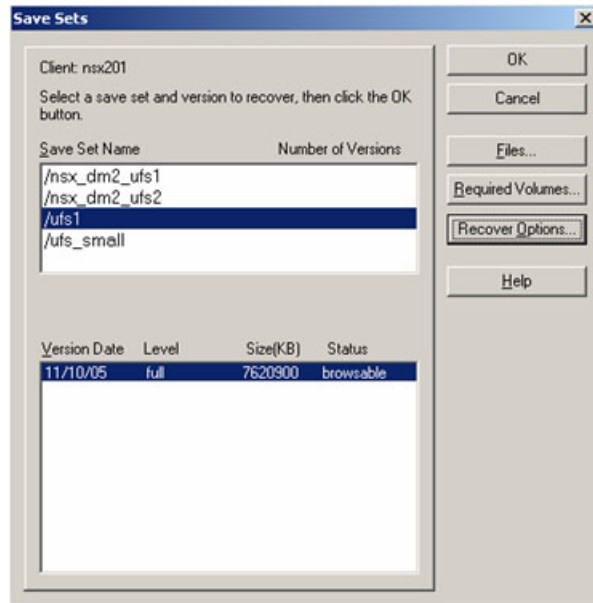

- a. From the **NetWorker Recover** window, click the **Options** drop-down list and select **Recover SaveSets**.
- b. Select the PFS to be recovered and click **Start Recover Operations**.

In Windows:

- a. From the **NetWorker Recover Client** menu, select **Save Set Recovery**. The **Save Sets** window appears.

- b. Select the PFS to be recovered and click **Recover Options**.

8. In the Relocate recovered data to this path field, specify the rawfs path by using this command syntax:

```
/.celerra_vol_ID
```

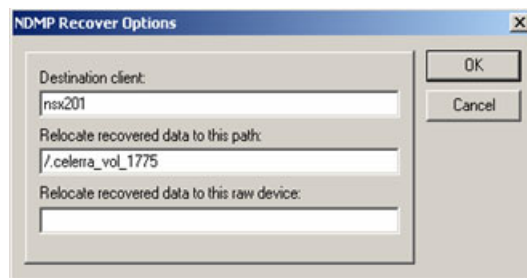

where:

*ID* = the volume ID of the rawfs

Example:

To specify the rawfs created earlier, type:

```
/.celerra_vol_1775
```

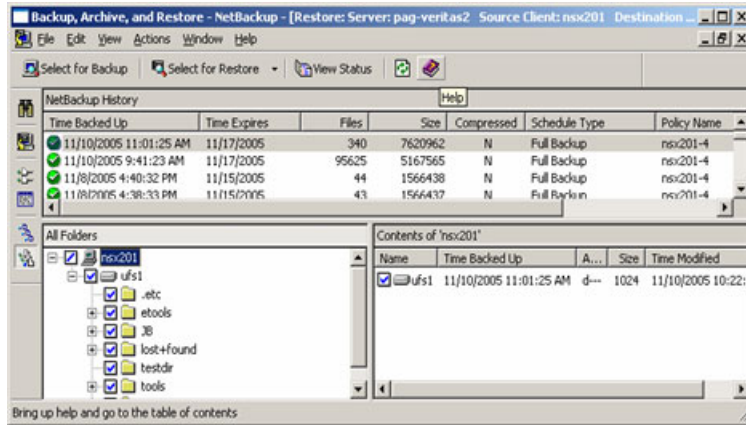

9. When the restore is complete, the client displays the message:

```
nsmdmp_recover: Successfully done
```

10. Symantec NetBackup procedure:

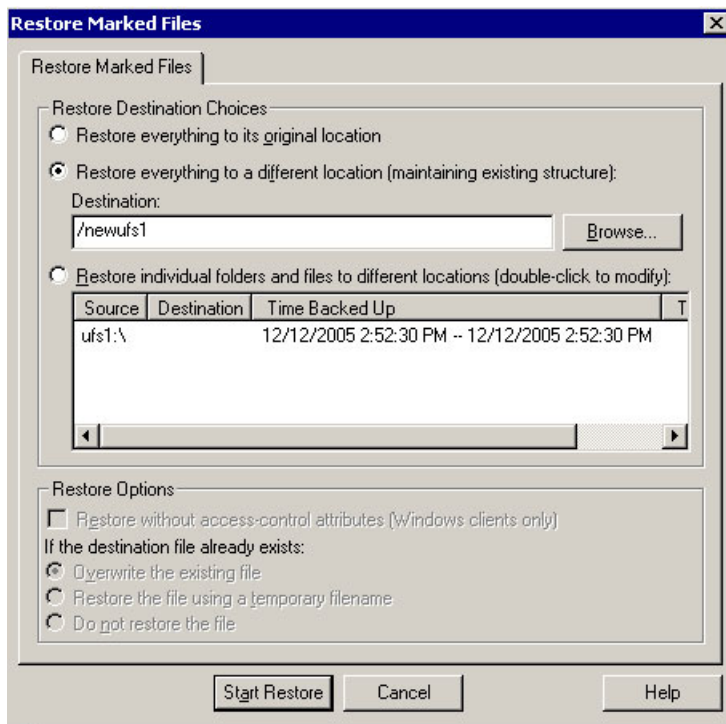

If you are performing a full destructive restore by using Symantec NetBackup software, perform steps 10 through 12.

From the **Backup, Archive, and Restore - NetBackup** window, select the file system to restore. Select the checkbox at the left of the file system name.

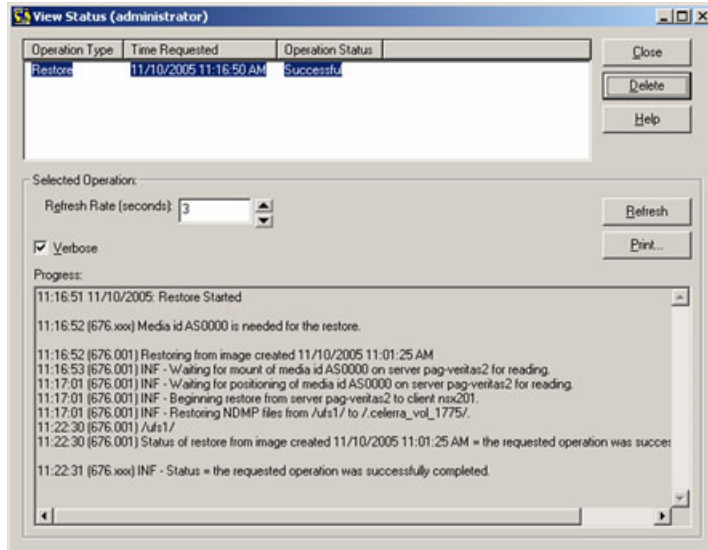

- From the **Restore Marked Files** window, select **Restore everything to a different location**.

Type `/.celerra_vol_ID`, where ID is the volume ID, without the leading "v" of the rawfs created earlier, and click **Start Restore**.

12. When the restore completes, the **View Status** window displays this information.

13. To convert the file system from a rawfs to a uxfs, when the restore is complete, type:

```
$ nas_fs -Type uxfs newufs1 -Force
```

Output:

```

id = 1151
name = newufs1
acl = 0
in_use = True
type = uxf
worm = off
volume = v1775
pool = clar_r5_performance
member_of = root_avm_fs_group_3
rw_servers= server_2
ro_servers=
rw_vdms =
ro_vdms =
auto_ext = no,virtual_provision=no
stor_devs = APM00043306037-000E,APM00043306037-
000D,APM00043306037-000A,APM00043
306037-0009
disks = d20,d10,d18,d8
disk=d20 stor_dev=APM00043306037-000E addr=c16t119
server=server_2
disk=d20 stor_dev=APM00043306037-000E addr=c32t119
server=server_2
disk=d20 stor_dev=APM00043306037-000E addr=c0t119
server=server_2
disk=d20 stor_dev=APM00043306037-000E addr=c48t119
server=server_2
disk=d10 stor_dev=APM00043306037-000D addr=c0t118
server=server_2
disk=d10 stor_dev=APM00043306037-000D addr=c48t118
server=server_2
disk=d10 stor_dev=APM00043306037-000D addr=c16t118
server=server_2
disk=d10 stor_dev=APM00043306037-000D addr=c32t118
server=server_2
disk=d18 stor_dev=APM00043306037-000A addr=c16t115
server=server_2
disk=d18 stor_dev=APM00043306037-000A addr=c32t115
server=server_2
disk=d18 stor_dev=APM00043306037-000A addr=c0t115
server=server_2
disk=d18 stor_dev=APM00043306037-000A addr=c48t115
server=server_2
disk=d8 stor_dev=APM00043306037-0009 addr=c0t114
server=server_2
disk=d8 stor_dev=APM00043306037-0009 addr=c48t114
server=server_2
disk=d8 stor_dev=APM00043306037-0009 addr=c16t114
server=server_2
disk=d8 stor_dev=APM00043306037-0009 addr=c32t114
server=server_2

```

14. The file system remains mounted on the Data Mover, but it is now automatically mounted read/write, as follows:

```
$ server_mount server_2
```

Output:

```

server_2 :
root_fs_common on /.etc_common uxf,perm,ro
ufs1 on /ufs1 uxf,perm,rw
newufs1 on /newufs1 uxf,perm,rw

```

15. You can verify the contents of the new file system from a CIFS or NFS client. To display the size and usage of the new file system from the Control Station, type:

```
$ nas_fs -s newufs1
```

Output:

```
total = 73855  
avail = 63501 used = 10354 (14%) (sizes in MB) (blockcount = 153600000)  
volume:  
total = 75000 (sizes in MB) (blockcount = 153600000)
```

---

Note: After the restore is done, the size of the rawfs will appear the same as the PFS. To view the actual raw file system size, extend it by a minimum of 1 MB, and then list the raw file system.

---

---

## Perform a full destructive restore of a VDM file system

Following are steps:

1. Create a raw file system the same size as the VDM PFS.
2. Mount the rawfs on the physical Data Mover, that is, server\_2, not the VDM.
3. Perform a FDR by using the same directions as for a non-VDM file system, described in [Perform full destructive restore on page 77](#).
4. Permanently unmount the rawfs from the physical Data Mover.
5. Create a mount point on the VDM.
6. Mount the rawfs on the VDM.
7. Convert the rawfs to a uxf.

---

## File-level restore

The restore time for performing a file-level restore by using an NVB is comparable to the time required to do the same by using a PAX backup.

The skipDedupFiles parameter of the vbb facility controls whether to skip the deduplicated files that are encountered during a file-level restore, thereby restoring at least the non-deduplicated files. If this parameter is set to 0, the restore is aborted when a deduplicated file is encountered. If it is set to 1, an error is logged and the restore process skips all

deduplicated files and restores any subsequent non-deduplicated files. The *Parameters Guide for VNX for File* provides more information.

### Temporary space requirements for a file-level restore

VNX requires temporary space to process metadata during the file-level restore process when an NVB serves as the backup source. The space needed is usually less than 2.5 percent of the overall backup image. By default, the restore target file system is used for the temporary space. Ensure that the file system has sufficient space for the temporary metadata before initiating the file-level restore.

VNX names the temporary space in the root of the file system.vbbtemp. It reads metadata about all the files from the tape into this space, creates and restores the requested files to the appropriate locations, and then cleans up the space when the restore completes. If the target file system becomes full during the restore, an error results.

---

Note: The NVB and the NVB full destructive restore processes do not require temporary space to process metadata. Files are guaranteed to be fully restored only when the restore process is complete. During the restore process, a file can exist, but all of its data may not be restored unlike PAX, which restores entire files at once. When an NVB is the backup source, entire trees are restored. The completeness of any file is not guaranteed until the entire restore process has finished.

---

## Exclude directories or files from backup by using filtering

[Filter to exclude directories or files from backup on page 32](#) provides information about excluding specific files or directories from being backed up. [Exclude a directory on page 86](#) describes the procedure to exclude a directory from backup, and [Exclude a file on page 88](#) describes the procedure to exclude a file from backup.

---

Note: The filtering feature is supported only by NDMP PAX (dump or tar) backup types. Do not use file and directory filtering with the NVB.

---

### Exclude a directory

You can increase the number of directory filters, up to 50, by using the filter.numDirFilter parameter. [Modify parameters on page 69](#) provides more information.

If you are using the VNX internationalization feature with a character set other than UTF-8, use the filter.dialect parameter to translate the pattern received to UTF-8. The default value of the parameter is ". After the pattern is converted to a UTF-8 pattern, the valid path rules are applied, and if the criteria are met, the pattern is accepted.

Action
To exclude a specific directory from the NDMP backup, type:

## Action

```
EMC_EDIR<nn>=/<valid directory pattern>
```

where:

*<nn>* = an ASCII number from 01 to 50 that helps you keep track of the total number of variable entries. By default, five variable entries are allowed per NDMP backup session for directory filtering.

*<valid directory pattern>* = a pattern that identifies the specific type of directory to be excluded from the backup.

Example:

To exclude the directory `ufs1/dir1` from the NDMP backup, type:

```
EMC_EDIR01=/ufs1/dir1
```

To exclude all directories that begin with "d ?" under `/ufs2`, type:

```
EMC_EDIR02=/ufs2/d*
```

## Exclude a file

You can increase the number of directory filters, up to 50, by using the `filter.numDirFilter` parameter. [Modify parameters on page 69](#) provides more information.

If you are using the VNX internationalization feature with a character set other than UTF-8, use the `filter.dialect` parameter to translate the pattern received to UTF-8. The default value of the parameter is `''`. After the pattern is converted to a UTF-8 pattern, the valid path rules are applied, and if the criteria are met, the pattern is accepted.

Action
<p>To exclude a specific file from the NDMP backup, type:</p> <pre><b>EMC_EFILE</b>&lt;nn&gt;= &lt;valid file pattern&gt;</pre> <p>where:</p> <p>&lt;nn&gt; = an ASCII number from 01 to 50 that helps you keep track of the total number of variable entries. By default, five variable entries are allowed per NDMP backup session for file filtering.</p> <p>&lt;valid file pattern&gt; = a pattern that identifies the specific type of file to be excluded from the backup.</p> <p>Example:</p> <p>To exclude all MP3 files from the NDMP backup, type:</p> <pre><b>EMC_EFILE01</b>=*.mp3</pre> <p>To exclude all files that begin with "temp ? from the backup, type:</p> <pre><b>EMC_EFILE02</b>=temp*</pre> <p>To exclude all WMA files from the backup, type:</p> <pre><b>EMC_EFILE03</b>=*.wma</pre>

## Perform tape silvering

Use tape silvering to restore the backup that is created on the source site by using the following software:

- ◆ [Restore with NetBackup on page 89](#)
- ◆ [Restore with CommVault Galaxy on page 93](#)
- ◆ [Restore with NetWorker on page 95](#)

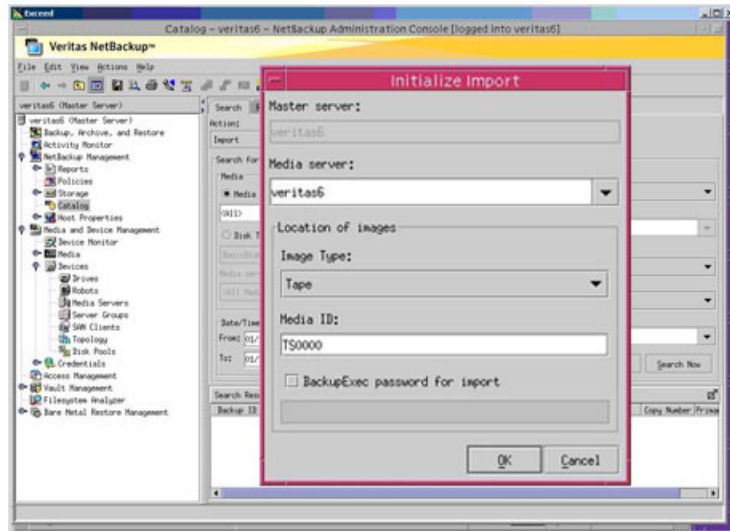

---

## Restore with NetBackup

Following are steps:

1. Physically place the tape volumes onto the destination TLU and then inventory the TLU to add new tape volumes to the NetBackup unit:
  - a. Start the **NetBackup Administration Console**. In a Windows environment, click **Start**, and select **Programs > Symantec NetBackup > NetBackup Administration Control**.
  - b. From the left panel, select **Devices** and then click **Robot**.
  - c. From the right panel, right-click the appropriate robot and then select **Inventory Robot** from the menu. The **Robot Inventory** window appears.
  - d. Under **Inventory Operation**, select **Update volume configuration** and then click **Start**.
  - e. Under **Results**, when the message **Volume configuration successfully updated** appears, click **Close**.
  - f. From the left panel, click **Media** and verify that the tapes are added in the media database.
2. Perform a Phase 1 import to scan the tape volumes containing the backup image and read the backup headers:
  - a. Select **NetBackup Management** and then click **Catalog**.
  - b. Click the **Search** tab and then select **Import** from the **Action** list box.
  - c. From the **Actions** menu, click **Initiate Import**. The **Initialize Import** dialog box appears.
  - d. Type the required information (for example, the tape volume ID of the first tape containing the backup image) in the **Media ID** field, and click **OK**. The **Confirm Initiate Import** window appears.

- e. Click **OK** to confirm the initialization process.
  - f. Click the **Results** tab to monitor the import process until it is completed successfully. Continue the import process until all the tape volumes are imported successfully.
3. Verify the backup images created in Phase 1 import:
    - a. Click the **Search** tab on the right panel, and then select **Import** from the **Action** list box.
    - b. From the **Policy type** list box, click **NDMP** and then click **Search Now**.
    - c. When the search is complete, the backup images are listed in the **Search Results** area. Select the required backup image to perform Phase 2 import.
  4. Perform a Phase 2 import to update the catalog with the required information:
    - a. From the **Actions** menu, click **Import**. The **Confirm Import** window appears.
    - b. Click **OK** to confirm the import.
    - c. Click the **Results** tab and monitor the import process until it has completed successfully.

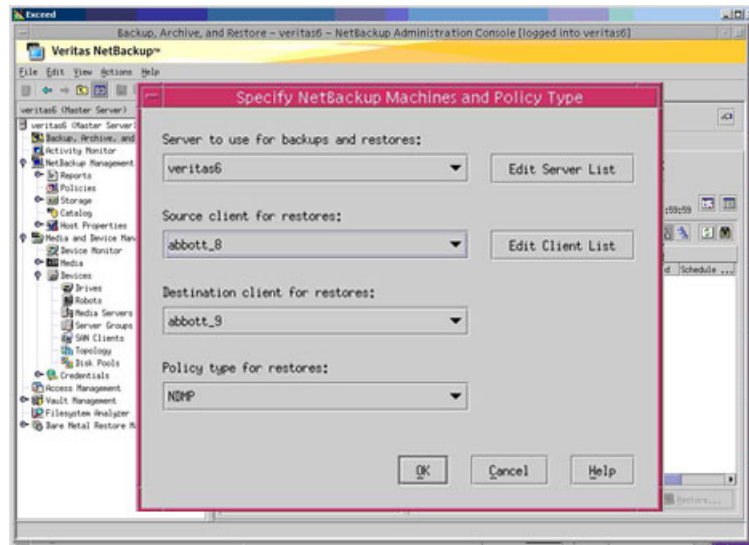

---

Note: Follow steps 5 through 10 to perform the restore operation.

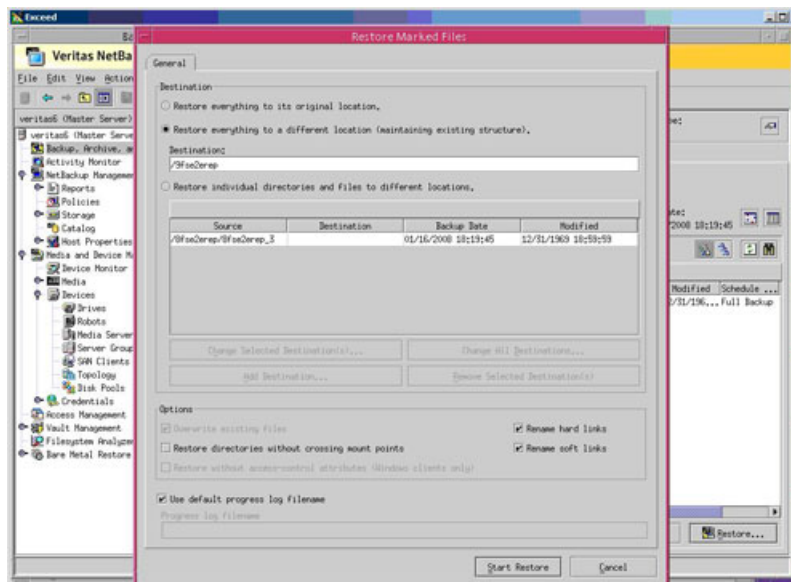

---

5. To perform the restore operation, from the left panel, select **Backup, Archive and Restore**.
6. From the right panel, click the **Restore Files** tab. The **Specify NetBackup Machines and Policy Type** window appears:
  - a. In the **Source client for restores** list box, select the original server as the source client for the restore operation. If the source client does not appear in the client list, click **Edit Client List** and enter the source client name.

- b. In the **Destination client for restores** list box, select the required destination server for the restore operation.
- c. In the **Policy type for restores** list box, select **NDMP**. Click **OK** to close the **Specify Net Backup Machines and Policy Type** window.

7. Under the **Directory Structure**, select the backup image to be restored, and then click **Restore**. The **Restore Marked Files** window appears.

8. Select the **Restore everything to a different location (maintaining existing structure)** option. In the **Destination** field, type the appropriate restore location as the destination file system for replication.

9. Click **Start Restore** to start the restore operation. The **View Progress** window appears. Click **OK** to view the progress of the restore operation.
10. From the left panel, select **Activity Monitor** and then double-click the listed job in the right panel. Click **Close** in the **Job Details** window, when the restore operation is complete.

## Restore with CommVault Galaxy

Perform the following steps to restore with CommVault Galaxy:

1. Create a subclient with the path:

```
/<mountpoint>/ts
```

where:

<mountpoint> = path to mount the file system on VNX.

Specify the mount point for the source file system in the backup definition with the postfix /ts. For example, if the primary file system is mounted on mountpoint replication\_pfs, the backup definition appears as:

```
Backup file system: /replication_pfs/ts
```

Note: The .ts is the default value for the server\_param NDMP tapeSilveringStr. You can change this value at any time. The source file system and checkpoints must be mounted on the NDMP Data Mover.

2. To create a file system replication session with the tape\_copy option, use this command syntax:

```
$ nas_replicate -create <name> -source -fs <fsName> -destination
-pool <dstStoragePool> -interconnect <name> -overwrite_destination
-tape_copy
```

where:

<name> = name of the replication session

<fsName> = name of the source file system

<dstStoragePool> = name of the destination storage pool

Example:

```
$ nas_replicate -create e2_g2_2 -source -fs newfs -destination -pool
clar_r5_economy -interconnect E2_G2 -overwrite_destination -tape_copy
```

Output:

```
OK
```

3. Run a full backup of the newly created subclient.
4. To capture the catalog information of the client for tape silvering, type:

```
C:\Program Files\CommVault\Galaxy\Base> qoperation capture -c <client
name> -dfn <db file name> -af n <answer file name>
```

Example:

```
C:\Program Files\CommVault\Galaxy\Base>qoperation capture -c eg2_DS -dfn
c:\Galaxy_CCM\eg2_db -afn c:\Galaxy_CCM\eg2_afile_capture
```

Output:

```
Capture successful
```

5. Copy the captured files to the destination site and then modify the answer file by entering the required information.
6. To merge the catalog information of the client in the Galaxy catalog at the destination site, type:

```
C:\Program Files\CommVault\Galaxy\Base>qoperation merge -dfn <db filename>
-afn <modified answer file name>
```

Example:

```
C:\Program Files\CommVault\Galaxy\Base>qoperation merge -dfn C:\Galaxy_CCM\eg2_db
-afn C:\Galaxy_CCM\eg2_afile_merge
```

Output:

```
Merge successful
```

7. Export media from the source library.
8. Import media in the destination library.
9. Browse the tape silvering backup in the destination setup to initiate the index retrieval job. When the job is complete, you can view the backup.
10. Select the <fs\_#> folder for restore and specify target server and path.
11. To start replication, when the restore process is complete, type:

```
$ nas_replicate -start <name> -overwrite_destination
```

where:

<name> = name of the replication session

Example:

```
$ nas_replicate -start e2_g2_2 -overwrite_destination
```

Output:

```
OK
```

## Restore with NetWorker

Perform the following steps to restore with NetWorker :

1. Ensure that there is a connection between the source and destination VNX systems.

On the source VNX Control Station, type:

```
nas_cel -name LA -create -ip 228.222.200.200 -passphrase pass1
```

On the destination VNX Control Station, source to root, type:

```
nas_cel -name NY -create -ip 192.168.100.100 -passphrase pass1
```

Note: Ensure that the passphrase is the same on the source and destination sites and that it is 6 to 25 characters in length.

Output:

	Source	Destination
Celerra	NY	LA
IP address	192.168.100.100	228.222.200.200

2. Create a Data Mover Interconnect between the source and destination Data Movers.

For example, if the source file system is mounted on server\_2 of the source VNX, and the destination file system is mounted on server\_3 of the destination VNX, create a Data Mover Interconnect from server\_2 of NY to server\_3 of LA, and vice versa.

On the source Control Station, type:

```
nas_cel -interconnect -create NYs2-LAs3 -source _server server_2
destination_system LA -destination _server server_3 -source _interfaces ip=
228.222.200.200 -destination _interfaces
ip= 192.168.100.100
```

Create a corresponding return interconnect from LA to NY :

```
nas_cel -interconnect -createLAs3 -Nys2 -source_server server_3 -destination
_system NY -destination _server server_2 -source_interfaces ip= 192.168.100.100
```

3. Start the replication session by using the tape\_copy option.

Note: Ensure that you start the replication session by using the tape\_copy option for the source file system, so that a common base checkpoint of the file system is backed up to tape. If it is not selected, the backup tape will not have the necessary objects to complete the tape silvering process and it will fail.

If you are using the Unisphere software to create a new replication session, ensure that you select the tape\_copy option. If you use CLI, type:

```
nas_replicate -create NY_src_fs_to_LA -source -fs NY_fs -destination -pool
clalr_r5_performance -interconnect NYs2-Las3 -tape_copy
```

4. To verify that the replication session is configured, type:

```
# nas_replicate -list
```

Output:

```
Name      Type  LocalMover  Interconnect  Celerra  Status
NY_src_fs file  server_2    ->NYs2-LAs2  LA       Info 26045317
_to_LA    system                                7429: stopped
```

5. Back up the source file system by using tape silvering method. [Configure EMC NetWorker on page 124](#) provides the procedure to set up NetWorker:
- In the NetWorker application, create an NDMP client for NDMP backup.
  - Click the **Apps and Modules** tab, and then type the username and password.
  - Type the following backup command:

```
nsrndmp_save -T ts
```

- d. Application information:

- HIST=y
- UPDATE=y
- SNAPSURE=y (optional)
- TS=y

---

Note: Make sure that the NDMP environment variable for tape silvering is set to TS=y.

---

- Start the backup operation. Verify that the Starting Tape Silvering (VSB) backup. [IsVsb] message appears in the server\_log of the Data Mover running the backup server. All server\_log messages will have the VSB session id in the log messages from here on.
- To verify that the backup is completed and savesets are created, run the mminfo command at command prompt.

Example:

```
C:\>mminfo -avV
```

Output:

```
volume      client      size level name
ssid       save time  date      time      browse  clretent
first      last file  rec volid  total fl
000057L2   server_2   440 GB    full /NY_fs
3785502540 1201811201 1/31/2008 3:26:41 PM 2/29/2008 1/31/2009
1048283320320 1499348067764 6 0 4171314420 1499348067765 tbN
000061L2   server_2   1023 GB   full /NY_fs
3785502540 1201811201 1/31/2008 3:26:41 PM 2/29/2008 1/31/2009
0 1048283320319 3 0 4188091594 1499348067765 hbN
bootstrap  eng252222 194 KB    full bootstrap
3735193758 1201834142 1/31/2008 9:49:02 PM 2/29/2008 1/31/2009
0 198399 3735193758 0 10553920 198400 cr
```

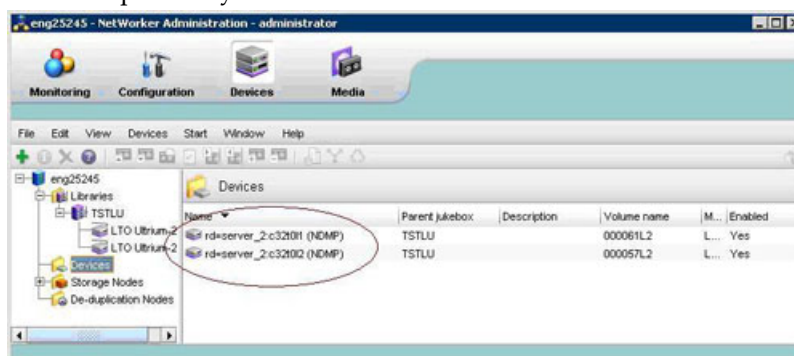

From the output the two tape volumes, 000061L2 and 000057L2, were used in the backup process, where:

000061L2 = header browse able NDMP (hbn) tape to mount on the tape volume

000057L2 = tail browse able NDMP (tbn) tape to mount on the tape volume

6. Transport the tapes to the destination site.
7. Merge the database of the backup application. Mount the tapes onto the tape library unit of the destination data center. The DMA server at the destination site does not have the catalog for these new tapes. Scan the tape and read the catalog information.

Physically mount the backup tapes (delivered from the source site) onto the destination NDMP tape library unit.

8. From the destination DMA server prompt, run the NetWorker scanner command:

```
scanner -m "rd=server_2:c32t011 (NDMP) "
```

where:

**server\_2:c32t011 (NDMP)** = the NDMP TLU that is configured

Output:

```
C:\>scanner -m "rd=server_2:c32t011 (NDMP) "
8909:scanner: using 'rd=server_2:c32t011 (NDMP)' as the device name
NDMP Service Debug: The process id for NDMP service is 0xdefe4a9c
8936:scanner: scanning LTO Ultrium-2 tape 000061L2 on rd=server_2:c32t011
```

9. To obtain the saveset id (SSID) from the backup tape, type:

```
mminfo -avV <tape name>
```

where:

<tape name> = name of the tape that is mounted on the NDMP TLU

Example:

```
mminfo -avV 00061L2
```

Output:

```

volume  client  size  level name ssid save time date
time browse clretent first last file rec volid total fl
000061L2 server_2 1042 MB full/1G 3850629539 1199829345 1/8/2008
4:55:45 PM 2/9/2008 1/9/2009 1067113652 3 0 4286834478 1067113653
crN

```

From the output the saveset id (SSID) is 3850629539.

10. To run inventory on the destination TLU slots that contain the tape 00061L2, on the destination DMA server, use this command syntax:

```
nsrjb -IEvvv -S <slot_number>
```

where:

<slot\_number> = slot number of destination TLU to run inventory

Example:

```
nsrjb -IEvvv -S 1-2
```

11. To find the client ID from the index that was scanned, use this command syntax:

```
mminfo -aS -q "ssid=<ssid>"
```

where:

<ssid> = saveset id obtained from the backup tape

To find the client ID from the index, type:

```
mminfo -aS -q "ssid=3850629539"
```

Output:

```

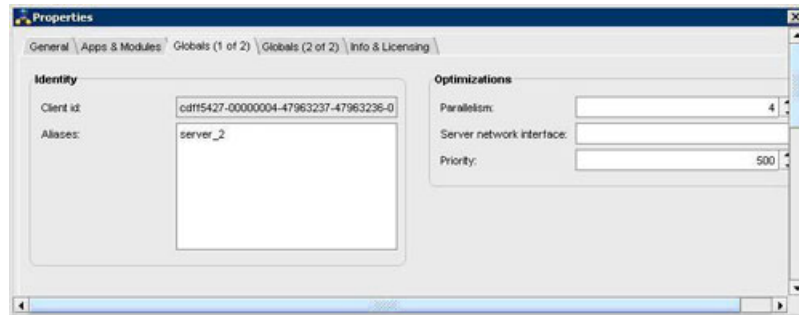

ssid=3850629539 savetime=1/8/2008 4:55:45 PM (1199829345)
server_2:/1G level=full sflags=vrNF size=1067113653 files=2
insert=1/9/2008 create=1/8/2008 complete=1/8/2008 browse=2/9/2008
2:41:08 PM retent=1/9/2009 2:41:08 PM
clientid=27aab1da-00000004-4783e62c-4783e62b-00010000-ac18fcde
*DIRECT: y, y;
*FILESYSTEM: /1G;
*HIST: y, y;

```

From the output, the client ID is 27aab1da-00000004-4783e62c-4783e62b-00010000-ac18fcde.

12. To create a new backup client:
  - a. In the **Properties** dialog box, click the **Globals (1 of 2)** tab and type the client ID in the **Client ID** field.
  - b. Type the server name of the hosts file in the **Aliases** field.

- c. Type the appropriate information for the rest of the tabs in the NeWorker client.

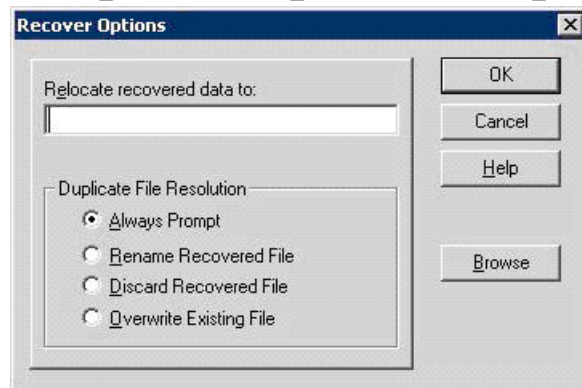

Note: If a backup client having the same name already exists, delete and re-create it.

13. To restore the saveset id from the backup tape, use NetWorker or type:

```
nsrndmp_recover -s <server name> -c <client name> -S <ssid>
-v -m <location for restore>
```

Example:

```
nsrndmp_recover -s win_server01 -c server_2 -S 3850629539 -v -m server_2::/NY_fs
```

Note: Ensure that the destination directory is set up correctly. If not, from the Options menu in NetWorker, click Recover Options, and then type the new directory name in the Recover Options dialog box.

14. Start restore to the destination file system and verify that the restore is completed successfully by using the server log of the destination Data Mover. Search entries with VSB labels in it.

Example:

```

2008-01-26 00:11:00: VSB: 6: Restore data verified[VsbRestoreTask:
:run, sessionId = 1]
2008-01-26 00:11:01: VSB: 6: Snap refresh done[VsbRestoreTask:
:run,1]
2008-01-26 00:11:01: VSB: 6: Successfully applied replication
signature to version[VsbTask::ApplyVersionSignature, sessionId=1]
2008-01-26 00:11:01: VSB: 6: Restore succeeded[VsbSession::Restore
OneVersion, 1]
2008-01-26 00:11:01: VSB: 6: Total restore data :323350 MB
[VsbRestoreTask::printStats, sessionId=0]
2008-01-26 00:11:01: VSB: 6: Restore time : 27572 Sec
[VsbRestoreTask::printStats, sessionId=1]
2008-01-26 00:11:01: VSB: 6: Restore speed is : 11 MB/s
[VsbRestoreTask::printStats, sessionId=1]

```

15. To start the replication session, from the source Control Station, use this command syntax:

```
# nas_replicate -start <replication_session_name> overwrite _destination
```

where:

<replication\_session\_name> = name of the replication session

Example:

To start the replication session, type:

```
# nas_replicate -start NY_src_fs_to_LA -overwrite_destination
```

Output:

OK

16. To verify that the replication session has started successfully, type:

```
# nas_replicate -list
```

Output:

Name	Type	Local Mover	Interconnect	Celerra	Status
NY_fs-to-41	filesystem	server_2	<--41s2-40s2	eng25240	Runing

As part of an effort to continuously improve and enhance the performance and capabilities of its product lines, EMC periodically releases new versions of its hardware and software. Therefore, some functions described in this document may not be supported by all versions of the software or hardware currently in use. For the most up-to-date information on product features, refer to your product release notes.

If a product does not function properly or does not function as described in this document, contact your EMC Customer Support Representative.

Topics included are:

- ◆ [EMC E-Lab Interoperability Navigator on page 102](#)
- ◆ [VNX user customized documentation on page 102](#)
- ◆ [Troubleshooting checklist on page 102](#)
- ◆ [Reporting a problem on page 103](#)
- ◆ [Known problems and limitations on page 104](#)
- ◆ [Error messages on page 104](#)
- ◆ [EMC Training and Professional Services on page 105](#)

## EMC E-Lab Interoperability Navigator

The EMC E-Lab™ Interoperability Navigator is a searchable, web-based application that provides access to EMC interoperability support matrices. It is available on EMC Online Support at <http://Support.EMC.com>. After logging in, in the right pane under **Product and Support Tools**, click **E-Lab Navigator**.

## VNX user customized documentation

EMC provides the ability to create step-by-step planning, installation, and maintenance instructions tailored to your environment. To create VNX user customized documentation, go to: <https://mydocs.emc.com/VNX>.

## Troubleshooting checklist

Review this checklist for tips on troubleshooting your NDMP backup:

- ◆ Is the backup or restore spanning multiple tapes? If yes, are more tapes available when the job spans to the next tape?
- ◆ Verify the TLU physical connections and correct any loose connections or incorrectly labeled hardware. [Set up the TLU on page 53](#) provides more information.

Verify the `server_log` to ensure that the parameters executed successfully. To read the `server_log` for a Data Mover, use this command syntax:

```
$ server_log <movername> | grep param
```

where:

`<movername>` = name of the specified Data Mover

[Configure the Data Mover on page 141](#) provides more information on setting parameters.

- ◆ Are the necessary parameters for NDMP and PAX set on the Data Mover? [Configure the Data Mover on page 141](#) offers more information.
- ◆ Ensure that the length of path including the filename of the source file does not have more than 4,095 bytes.
- ◆ Confirm in the E-Lab Interoperability Navigator that VNX, backup software version, and hardware are supported for NDMP backups with VNX.
- ◆ Have you created the usernames and passwords on all NDMP-Host Data Movers? [Assign a username and a password to a Data Mover on page 56](#) provides more details. Have you used the same usernames and passwords when configuring Data Mover access in the backup software?

- ◆ Have the TLU device names been recorded correctly and typed during configuration of the backup software? [Set up the TLU on page 53](#) and your backup software vendor documentation provide more information.
- ◆ If your backup vendor supplies utilities for verifying the physical and logical paths between the backup server and the TLU devices, confirm that these paths are valid.
- ◆ Test a backup or restore by using VNX server\_archive utility. By eliminating the NDMP protocol, you are able to eliminate possible problems and more easily troubleshoot issues. *Using the server\_archive Utility on VNX* explains how to use this utility.
- ◆ If using the SNAPSURE=y environmental variable (or manually by using a checkpoint for the backup), and the checkpoint in use is refreshed, unmounted, or deleted, the backup fails and a message is sent to the event log. (*Using VNX SnapSure* provides information on troubleshooting checkpoint creation failure.)
- ◆ If a timeout occurs while creating a checkpoint, an UNMOUNT\_AND\_DELETE event is sent to the Control Station. The backup fails and the failure is recorded in the server\_log. If the checkpoint is actually created after timeout, it will be deleted by the event.

If the backup still does not work correctly after you verify these things, contact the backup software vendor for further support.

---

## Reporting a problem

Problem Resolution Roadmap for VNX identifies troubleshooting resources and processes. In addition to the general information in Problem Resolution Roadmap for VNX, gather these backup-specific information before reporting a problem to the EMC Support Center:

- ◆ At what stage did the problem occur?
- ◆ What is the version and patch number of your backup software?
- ◆ Is your backup software installed on a UNIX or Windows platform?
- ◆ What is the IP and hostname of the system running the backup software?
- ◆ Are you backing up CIFS files, NFS files, or both?
- ◆ What model is the TLU?
- ◆ Does your environment have a two-way or three-way backup configuration?

## Known problems and limitations

Table 5 on page 104 describes known problems that can occur when using NDMP backups and presents workarounds.

**Table 5. Known problems and workarounds**

Known problem	Symptom	Workaround
A full restore recovers only data from the last full backup. The restore does not include subsequent incremental backup data.	You run a full restore, and incremental backup data is not included with the restored data.	Perform a separate restore of the incremental backup data.

## Error messages

All event, alert, and status messages provide detailed information and recommended actions to help you troubleshoot the situation.

To view message details, use any of these methods:

- ◆ Unisphere software:
  - Right-click an event, alert, or status message and select to view Event Details, Alert Details, or Status Details.
- ◆ CLI:
  - Type `nas_message -info <MessageID>`, where `<MessageID>` is the message identification number.
- ◆ *Celerra Error Messages Guide*:
  - Use this guide to locate information about messages that are in the earlier-release message format.
- ◆ EMC Online Support:
  - Use the text from the error message's brief description or the message's ID to search the Knowledgebase on [EMC Online Support](#). After logging in to EMC Online Support, locate the applicable **Support by Product** page, and search for the error message.

---

## EMC Training and Professional Services

EMC Customer Education courses help you learn how EMC storage products work together within your environment to maximize your entire infrastructure investment. EMC Customer Education features online and hands-on training in state-of-the-art labs conveniently located throughout the world. EMC customer training courses are developed and delivered by EMC experts. Go to EMC Online Support at <http://Support.EMC.com> for course and registration information.

EMC Professional Services can help you implement your system efficiently. Consultants evaluate your business, IT processes, and technology, and recommend ways that you can leverage your information for the most benefit. From business plan to implementation, you get the experience and expertise that you need without straining your IT staff or hiring and training new personnel. Contact your EMC Customer Support Representative for more information.

# Configure your Backup Software

This appendix lists restrictions and configuration steps for the various backup software vendors EMC-qualified for NDMP backups with VNX. The E-Lab Interoperability Navigator is the definitive source for information on NDMP backup software vendor qualification.

These guidelines apply to all backup software vendors:

- ◆ Use the same password used in [Assign a username and a password to a Data Mover on page 56](#).

- ◆ Use this format for device names, which VNX uses to address a TLU device:

```
<SCSI_controller> <SCSI_ID> <SCSI_LUN>
```

where:

<SCSI\_controller> = chain number of the controller

<SCSI\_ID> = SCSI ID (target) of the controller

<SCSI\_LUN> = logical unit number (LUN) of the controller

- ◆ Configure port 10000 for NDMP operations. VNX uses dynamic port allocation from the Data Mover for NDMP three-way backups and restores.
- ◆ Use the Data Mover name as the hostname, for example, server\_2.

Topics included are:

- ◆ [Terminology differences on page 109](#)
- ◆ [Configure Atempo Time Navigator on page 109](#)
- ◆ [Configure BakBone NetVault on page 113](#)
- ◆ [Configure CA BrightStor ARCserve Backup on page 114](#)
- ◆ [Configure CommVault Galaxy on page 117](#)
- ◆ [Configure EMC Data Manager with NDMP on page 120](#)
- ◆ [EMC NetWorker on page 124](#)

- ◆ [Fujitsu-Siemens NetWorker on page 131](#)
- ◆ [Configure HP OpenView Storage Data Protector on page 132](#)
- ◆ [IBM Tivoli Storage Manager on page 135](#)
- ◆ [Configure Syncsort Backup Express on page 141](#)
- ◆ [Configure Symantec NetBackup on page 143](#)
- ◆ [Configure Symantec Backup Exec on page 154](#)

## Terminology differences

[Table 6 on page 109](#) lists terminology differences that exist between this document and the third-party documentation.

**Table 6. Terminology differences**

EMC term	Equivalent third-party terms
Tape library unit (TLU), jukebox, tape drive	Library (refers to any backup storage device), autochanger handle, autochanger
TLU robot	Robotic arm, arm changer
NDMP-Host Data Mover	VNX filer, NAS filer, application server
VNX	Client computer, VNX filer

## Configure Atempo Time Navigator

The procedures for configuring Time Navigator are based on Atempo Time Navigator version 4.2. These procedures describe how to configure NDMP backups by using VNX and Atempo Time Navigator.

For information on how to set environment variables for Atempo Time Navigator, see [Set environment variables on page 58](#).

The tasks to configure Atempo Time Navigator are:

1. [Create the file server on page 110](#)
2. [Create and configure a library on page 110](#)
3. [Configure the drives on page 111](#)
4. [Create a media pool on page 111](#)
5. [Create the Time Navigator client on page 112](#)

---

## Create the file server

1. From the **Time Navigator Administration** application, select **Platform** ► **New** ► **Host** to open the **New Host** window.
2. In the **General** tab, type the following information:
  - **Type list:** Select the file server type.
  - **Host Name:** Type the Data Mover name, for example, server\_2.
3. In the **Protocol** tab, the NDMP box is selected. Choose the NDMP version and type the following information:
  - **User:** Type **ndmp**
  - **Password:** Type the password that you used in [Assign a username and a password to a Data Mover on page 56](#).
  - **Confirm:** Retype the password.
4. In the **Advanced** tab, the **Backup Master** option is automatically selected. Select **Server** if the NDMP client is installed on the **Time Navigator** server, else select **Host** and provide the name of the Time Navigator client acting as the Backup Master in the **Master Name** field.
5. Click **OK**.
6. Right-click the host icon you have just created, and select **Enable**.

---

## Create and configure a library

1. From the **Time Navigator Administration Console**, select the NDMP host that you created in [Create the file server on page 110](#).
2. Select **Devices** ► **Library** ► **New** and then select a library type to open the **New Library** window.
3. Type the **Library** name and the **Device Descriptor**. The device descriptor uses the format:  
`<SCSI_controller> <SCSI_target> <LUN>`  
[Set up the TLU on page 53](#) provides more information.
4. Associate the previously created drives to the library.

5. Click **OK**. Time Navigator performs a reinitialization of the library. You can also use the **Time Navigator Device Detection Wizard** to detect and help you configure your library. In the **Time Navigator Administration Console**, select **Devices** and then select **Device Detection Wizard**.

---

## Configure the drives

1. In **Time Navigator Administration Console**, select the file server host (Data Mover) that you created in [Create and configure a library on page 110](#).
2. Select **Devices** ► **Library** ► **New**, and then select a drive type to open the **New Drive** window.
3. Type the appropriate information in the fields. For device descriptor use the format:  
`<SCSI_controller> <SCSI_target> <LUN>`  
[Set up the TLU on page 53](#) provides more information.
4. Click **OK**.
5. Right-click the drive icon and select **Enable**. Repeat the procedure if you are creating more than one drive.

---

Note: You can also use the **Time Navigator Device Detection Wizard** to detect and configure your drives. From the **Time Navigator Administration Console**, select **Devices** and then select **Device Detection Wizard**.

---

---

## Create a media pool

1. From the **Time Navigator Administration Console**, select **Storage** ► **MediaPool** ► **New** to open the **New Media Pool** window.
2. Type the necessary information and ensure that you associate the media pool to the previously created drives.
3. Click **OK**.

---

## Create the Time Navigator client

1. From the **Time Navigator Administration Console**, select the host where you want to create the **Time Navigator Client** for NDMP application.

---

**Note:** Do not select the NDMP server, as the host should be able to run the tina\_daemon, which the NDMP server cannot do.

---

2. Select **Platform ► New ► Application**.
3. Select the NDMP application.
4. Click **OK**. The **New Application** window appears.
5. Type the following information:
  - **Host Name:** Name of the host where Time Navigator resides. The same system you selected in step 1.
  - **Application Name:** Name of the NDMP application.
  - **Comment:** Comment concerning the application you are creating.
  - **NDMP Server:** The NDMP-Host Data Mover you want to back up.
  - **NDMP User Name:** Type ndmp, which is also the username you entered for the NDMP-Host Data Mover in [Assign a username and a password to a Data Mover on page 56](#).
  - **NDMP Password:** Password you typed for the NDMP-Host Data Mover in [Assign a username and a password to a Data Mover on page 56](#).
  - **Local User:** Name of an operating system user who can access the host where the NDMP application resides.
  - **Password:** Password for the username you typed in the previous field.
6. Click **OK**.
7. Right-click the NDMP application and select **Enable**.

---

## Configure BakBone NetVault

The procedures for configuring BakBone NetVault are based on NetVault version 7.1. They describe how to configure your BakBone NetVault software for NDMP backups with VNX.

When performing NDMP backups with the VNX and BakBone NetVault, version 6.3 or later of the NDMP Application Module (APM) must be installed on the client running the NetVault backup software.

The EMC E-Lab Interoperability Navigator provides a list of qualified APM versions. NetVault documentation provides information on installing the NDMP APM.

The tasks to configure BakBone NetVault are:

- ◆ [Add an NDMP server on page 113](#)
- ◆ [Use the automatic device configuration on page 114](#)

---

### Add an NDMP server

1. From the main **NetVault** window, double-click the **Backup** icon. The **NetVault Backup** window appears.
2. Double-click the BakBone client name.
3. Right-click the NDMP client and select **Add Server**.
4. In the **NDMP server** dialog box, type the required information:
  - **Name:** Name of the NDMP-Host Data Mover.
  - **Address:** IP address of the NDMP-Host Data Mover.
  - **Port:** NDMP server port number, which you must set as **10000**.
  - **Account:** The username, which must match the one you set for the NDMP-Host Data Mover.
  - **Password:** Password for the username account, which must match the password you set for the NDMP-Host Data Mover.
5. Click **OK**.

---

## Use the automatic device configuration

NetVault 7.1 automatically locates the devices on the network. After you add the NDMP server, complete the procedure in this section, which describes how to recognize and configure a device by using the NetVault wizard. BakBone NetVault documentation provides information about how to manually recognize and configure devices in the following steps:

1. Double-click **Device Management** to open the **NetVault Device Management** window.
2. From the **Add** menu, select **Add Library**. The **Add Library** window appears.
3. From the **Library Selection** tab, double-click **BakBone client**.  
Under **Ndmp Tape**, select the correct drive to which you want the drive-bay value assigned.
4. Double-click the library you want to configure.
5. Click the **Drive Selection** tab.
6. Double-click **BakBone client**.
7. By using the **Select for drive bay**, select or type a valid drive-bay value.
8. Under **Ndmp Tape**, select the correct drive to which you want the drive-bay value assigned.
9. Repeat steps 7 and 8 to assign a drive-bay value to each possible drive in that library.
10. Click the **Configuration** tab.
11. Right-click the library, and select **Scan for shared drives**.
12. Click **OK**, and then click the **Save** details icon in the top-left corner.
13. In the **Library added successfully** dialog box, click **OK**, and then close the **Add Library** window.

---

## Configure CA BrightStor ARCserve Backup

CA BrightStor ARCserve Backup configuration procedures are based on CA BrightStor ARCserve Backup version 11.1:

1. [Configure the NDMP devices on page 115](#)
2. [Configure the nas.cfg file on page 116](#)
3. [Add a Data Mover to ARCserve Backup on page 117](#)

---

Note: Filters are unsupported when performing NDMP backups with VNX and CA BrightStor ARCserve Backup. If you are using the version 5.4.21.0 or later, ensure that the NDMP parameter `v4OldTapeCompatible` is set to 0. If you plan to use Dynamic Drive Sharing, set the NDMP `scsiReserve` parameter to 0 on the Data Mover running version 5.1 or later, where devices are connected. [Modify parameters on page 69](#) explains how to change parameter settings.

---

## Configure the NDMP devices

1. From the **BrightStor ARCserve Backup** home page, click **Configuration** to expand the Configuration subtopics.
2. In **Configuration**, click **Device Configuration Wizard**.
3. On the **Welcome** screen, select **Windows Server** and click **Next**.
4. In **Options**, select **NAS Servers** and click **Next**.

This message appears:

```
Tape Engine service will be stopped in order to allow device
configuration. Would you like to continue?
```

5. Click **Yes**, which stops any other backups that are running.
6. In **NAS Server Configuration**, click **Add** and select **NAS Server**.
7. In the **Device Configuration** dialog box, in **Server Configuration**, click **New Server** and type the name of the Data Mover.
8. In the **User** column, type the username that you have created for the NDMP-Host Data Mover.
9. Double-click **Password** and type the same password that you have created for the NDMP-Host Data Mover in the **Password** field.
10. Type the password again in **Confirm password**, and click **OK**.
11. Select **Continue** to configure libraries and click **Next**.  
**Tape Library Option** appears, which can take a few minutes.
12. Ensure that the proper devices appear in the **Library devices** box and click **Next**.
13. In **Assign cleaning tape**, click **Properties**, select the properties appropriate for your environment, and click **OK**.
14. Click **Next**.

15. Select or clear **Library Quick Initialization**, depending on your configuration, and click **Next**.
16. Click **Finish**, and then click **Exit**.
17. Click **Yes** and then start the tape engine when the following message appears:

```
Exit Device Configuration?
```

---

### Configure the nas.cfg file

You can configure the nas.cfg file to perform partial-volume backups. This backup type requires that you type the paths in the configuration file.

1. Open the nas.cfg file. This file is located in the `<base_install>\NAS Option` folder.
2. On the first line, type the name of the Data Mover.
3. On separate lines, type each absolute path, starting with the logical device name. Use this format:

```
<moveiname> /volume1/folder1/folder2 /volume2/folder3/folder4
```

where:

```
<moveiname> = name of the Data Mover
```

---

**Note:** To end each server configuration, type a semicolon.

---

Example:

```
server_2 /volume1/folder1/folder2/ volume2/folder3/folder4
```

4. Save the file.
5. To run a backup, use the Backup Manager to configure and submit a backup. Select a Data Mover (VNX) as your source and the tape device as the target. The tape device can be connected to the same VNX or to another VNX.

---

## Add a Data Mover to ARCserve Backup

1. From the **BrightStor ARCserve Backup** home page, in **Quick Start**, click **Backup**.
2. Click **Source**, right-click **NAS Servers**, and select **Add Machine/Object**.
3. In **Add Server**, type the name of the Data Mover.
4. Select the appropriate settings for your configuration, click **Add** and then click **Close**.  
The Data Mover name should appear under the NAS Servers heading on the **BrightStor ARCserve Backup** home page.
5. Double-click the Data Mover you added in step 4, and then in the **Security** dialog box, type the username; then type the password.

---

**Note:** You must use the same username and the same password you typed in [Assign a username and a password to a Data Mover on page 56](#).

---

---

## Configure CommVault Galaxy

CommVault Galaxy is not compatible with the Volume-Level Copy (VLC) feature, which is an environment variable setting. This restriction applies when performing NDMP backups with VNX and CommVault Galaxy.

The procedures herein are based on an autodetect configuration of CommVault Galaxy version 7.0.

---

**Note:** If you have a license for SCSI-3 Reserve with CommVault Galaxy version 5.9 or later, and you plan to use Dynamic Drive Sharing with CommVault Galaxy, set the NDMP scsiReserve parameter to 0 on the Data Mover, running version 5.1 or later, where devices are connected. [Modify parameters on page 69](#) explains how to change this parameter.

---

The tasks to configure CommVault Galaxy are:

1. [Add a client on page 118](#)
2. [Configure the TLU and tape drives for NDMP operations on page 118](#)
3. [Test the TLU device on page 120](#)

---

## Add a client

1. From **CommCell Browser**, right-click **Client Computers** and select **New Client**. The **Add New Client** window appears.
2. Select **NAS Client** and click **OK**. The **Add NDMP Server** window appears.
3. Specify the attributes:
  - **NDMP server Hostname**: Hostname of the NDMP server.
  - **NDMP Login**: Type the same username you created for the NDMP-Host Data Mover.
  - **NDMP Password**: Type the same password you created for the NDMP-Host Data Mover.
4. Confirm the password, and then click **Detect**.

The system detects the EMC VNX as vendor and displays the firmware revision, which is the VNX software running on the NDMP server. It also displays the listen port, which appears as 10000.
5. If all the information is correct, click **OK**. If not, click **Cancel**.

The newly added server appears in CommCell Browser.

---

## Configure the TLU and tape drives for NDMP operations

1. From **CommCell Browser**, select **Tools** ► **Control Panel**. Select and double-click **Library and Drive Configuration**.

The **Library and Drive Configuration** window appears.
2. Select the **MediaAgents** window.
3. Select the media agent to which you want to associate the library, and click **Add** to move the selection to the **Selected MediaAgents** side. Click **OK** to close the window.
4. From the **Galaxy Library** window, click **Start** ► **Detect/Configure Devices**. The **Detect Library** window appears.
5. Click **NDMP Devices**, and click **OK**. The **Select NDMP servers to Detect** window appears with a list of NDMP servers.
6. If the desired NDMP servers appear in this list, select them, click **Add** to move them to the selected NDMP servers side, and click **OK**. A confirmation window appears asking if you want to continue. Go to step 10.

If the desired NDMP server does not appear in the list, click **Update NDMP Host List** to refresh the server list and try again.

The **NDMP server List** window appears.

7. Click **Add**. The **Add NDMP server** window appears.
8. Type the **NDMP server Hostname**.  
Type the **NDMP Login**, which should be the same username you created in [Assign a username and a password to a Data Mover on page 56](#).  
Confirm the password, and then click **Detect**.
9. The system detects the EMC VNX as vendor, and displays the firmware revision, which is the VNX software running on the NDMP server. It also displays the listen port, which appears as 10000.  
If all the information is correct, click **OK**. If not, click **Cancel**. The **NDMP server List** window reappears, listing the newly added server.
10. Repeat steps 7 and 8 for each new server you want to add. After all the required servers are added, click **Close**. The **Select NDMP Servers to Detect** window reappears. Click **OK**.  
A confirmation window appears asking if you want to continue.
11. If so, click **Yes**. The **Processing** window appears showing the progress and time to complete. This can take time, depending on the number of devices to detect.  
The **Log** window appears showing the log of the operation.
12. Click **Close**. An information window appears stating: "Right-click on a particular device to continue with its configuration." Click **OK**.
13. From the **Library and Drive Configuration** window, click **Libraries** to view the newly added libraries beside the yellow library icon. The question marks mean the library is not yet fully configured.
14. Expand the libraries to view the details and ensure that all required tape drives are shown under the library.
15. Configure the library by right-clicking the library and selecting **Configure**. Complete the information requested.
16. Click **Start ► Exit** and close the control panel.

---

## Test the TLU device

1. After you configure the library, ensure that the library is accessible to CommVault Galaxy.  
From **Control Panel**, select and double-click **Library and Drive Configuration**. The **Library and Drive Configuration** window appears.
2. Select the **MediaAgents** window.
3. Select the media agent to which you want to associate the library and click **Add** to move the selection to the **Selected MediaAgents** side. Click **OK** to close the window.  
The newly added library appears.
4. From the **Galaxy Library** window, right-click the library and select **Validate**.  
The **Confirm Validate** window appears stating: Validating a library will mount a media in each drive and can take several minutes per drive. Are you sure you want to validate drives in library.
5. Click **Yes**. The **Processing** window appears showing the progress of validation, and then the **Log** window appears.
6. Click **Close**.  
If the validation fails, a window appears displaying the error message. Click **OK**. Verify the log and click **Close**.
7. To end the session, click **Start ► Exit**.

---

## Configure EMC Data Manager with NDMP

EMC Data Manager (EDM) is a high-performance backup solution optimized for high-end UNIX and Windows NT environments. EDM offers centralized management of scheduling, monitoring, reporting, and configuring for all NDMP backups. It initiates data movement that is then performed by the NDMP software on VNX, thus distributing resource usage and freeing the EDM for other backup tasks. File server clients are never affected by backup processing, allowing users uninterrupted operation.

You can configure EDM to have NDMP send data directly to a TLU attached to VNX, or to use the the network to transport data from one file server to another, and then to a TLU attached to the secondary file server. With EDM and NDMP, data flows from the system to the Data Mover, and then directly to the VNX-attached TLU through ultra fast-wide SCSI or Fibre Channel connections. Network congestion is minimized because the data path and control path are separated. Backup can occur locally, from VNX to the tape drives, while management occurs centrally from a single EDM backup server.

With EDM support for VNX:

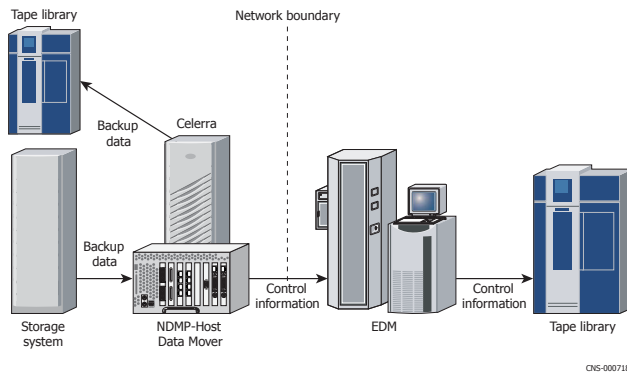

- ◆ EDM backs up all VNX native attributes, including NFS and CIFS/NT attributes and ACLs.
- ◆ Data moves from disk to local tape through the NDMP server, eliminating the need to move the backup data over the network.

EDM allows you to use one of two hardware configurations with VNX:

- ◆ Local backups
- ◆ Three-way backups

## Local backups with EDM

In the local backup, data transfer occurs between the Data Mover and the TLU over ultra fast-wide SCSI or Fibre Channel connections. This configuration is achieved by attaching drives from a TLU to each NDMP-Host Data Mover in the configuration. Each NDMP host runs all NDMP services such as data and tape/mover. [Figure 10 on page 121](#) illustrates an EDM NFS backup.

**Figure 10. EDM NFS backup**

## Three-way backups with EDM

In the centralizing EDM configuration shown in [Figure 11 on page 122](#), you can transfer all backup data to a single TLU even if the data is served from more than one VNX. Bandwidth is limited to the bandwidth available on the LAN that is used to transfer the data.

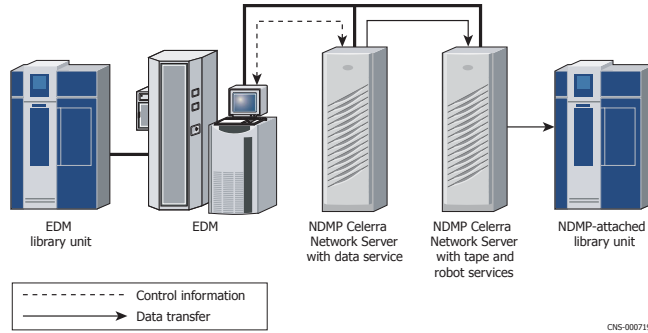

Figure 11. Three-way backups with EDM

## EDM restrictions

These restrictions apply when performing NDMP backups with VNX and EDM:

- ◆ Configuring the same NDMP-attached TLU on more than one EDM is not supported. This causes unpredictable results and can cause data loss.
- ◆ The `bufsz` parameter setting on VNX must be at least 128 KB, which is the default. [Configure the tape buffer size on page 46](#) explains how to change this parameter.
- ◆ The `readWriteBlockSizeInKB` parameter setting on VNX must be at least 128. [Configure the read or write block size on page 47](#) explains how to change this parameter.
- ◆ Stand-alone drives are unsupported, drives must reside in a TLU.
- ◆ The TLU robot must be connected to the EDM only through VNX. Connecting the NDMP TLU robot directly to the EDM system is unsupported.
- ◆ The EDM-attached TLU used to back up the EDM and to perform network, Symmetrix Path, and Symmetrix Connect backups and restores cannot be the same TLU used to perform NDMP backups. Do not attempt to share the TLU used to back up the EDM and perform other types of EDM backups with the NDMP solution.
- ◆ Incremental backups from VNX cannot detect filename changes or deleted files. Therefore, multiple files can be restored if filenames were changed or files were deleted.
- ◆ EDM version 5.1 or later is required for NDMP backups with this version of VNX.

This section assumes the robot is directly attached to the NDMP-Host Data Mover. The EDM documentation noted in [Related Information on page 16](#) provides more details on this procedure.

To configure your TLUs:

1. Run **Imconfig**.
2. When the **EMC Library Manager Configuration Tool** menu appears, select the **AUTOCONFIG** option, and then note the information that follows.

---

Note: The LIST option does not display NDMP devices in the unconfigured devices list because they are not locally attached.

---

---

## Install and configure the EDM client

Follow the EDM documentation to install and configure the client.

Before you can perform NDMP backups, EDM must have access to each Data Mover involved in the backup process.

Perform the following steps to install and configure the EDM client:

1. Type a trusted account username and password in the **EDM Configuration Wizard** when prompted. The username and password should match those assigned to each NDMP-Host Data Mover.
2. Run **Imconfig** to configure your TLUs. The **EMC Library Manager Configuration Tool** appears.
3. Select **AUTOCONFIG** and note the information that follows.

---

Note: The **EDM Configuration Wizard** automatically locates and tests the TLU connections.

---

## EMC NetWorker

These restrictions apply when performing NDMP backups with VNX and EMC NetWorker:

- ◆ The `bufsz` parameter setting, which is called block size in NetWorker documentation, must be set based on the tape drive vendor. [Tape drive buffer sizes on page 129](#) lists the settings for different tape drives. [Configure the Data Mover on page 141](#) shows how to set the `bufsz` parameter.
- ◆ VNX allows only one device name per robot and one device name per tape drive. Use this device name when configuring the robot or a tape drive for the NDMP backup software. The name for this device should be an entity that can be resolved through the network, such as `server_2:c1t0l0`, where:
 

`server_2` = customer-assigned Data Mover name `c1t0l0` = robot or tape device name
- ◆ Ensure that the HIST and DIRECT environmental variables are enabled prior to the backup to make DAR available for file recovery.

## Configure EMC NetWorker

The procedures for configuring NetWorker for NDMP backups with VNX are based on NetWorker version 7.3.x or later:

1. From a Windows backup client running NetWorker, type:

```
<networker_install_path>\bin\directory
```

From a UNIX backup client running NetWorker, proceed to step 2.

2. At the prompt, type:

```
# jbconfig
```

To complete the `jbconfig` script, you need:

- The password for the NDMP-Host Data Mover where the tape device is attached. This is the password you set in [Assign a username and a password to a Data Mover on page 56](#).
  - The SCSI device name. [Set up the TLU on page 53](#) provides information on accessing device names.
3. When prompted, select the **Autodetect NDMP SCSI Jukebox** option.
  4. Complete the interactive `jbconfig` script. Use the [Sample jbconfig script on page 125](#) as an example.

## Sample jbconfig script

The NetWorker configuration script looks similar to the example in this section. Within the script, bold text indicates user entry. Brackets indicate default values. You can press Enter to accept a default value, or you can type the value:

```
Script started on Mon Aug 27 15:09:13 2007

# jbconfig

Jbconfig is running on host ohnetworker (SunOS 5.8),
and is using ohnetworker as the NetWorker server.
  1) Configure an AlphaStor Library.
  2) Configure an Autodetected SCSI Jukebox.
  3) Configure an Autodetected NDMP SCSI Jukebox.
  4) Configure an SJI Jukebox.
  5) Configure an STL Silo.

What kind of Jukebox are you configuring? [1] 3

Enter NDMP Tape Server name: ? scarlos5

Installing 'Standard SCSI Jukebox' jukebox - scsidev@0.0.0.

What name do you want to assign to this jukebox device?
Garbage

NDMP Service Debug: The process id for NDMP service is
0xbbb633c0

NDMP Service Debug: The process id for NDMP service is
0xbbb633c0

15814:jbconfig: Attempting to detect serial numbers on
the jukebox and drives ...

15815:jbconfig: Will try to use SCSI information returned
by jukebox to configure drives.

Turn NetWorker auto-cleaning on (yes / no) [yes]?

The following drive(s) can be auto-configured in this
jukebox:

1> 4mm @ 0.0.1 ==> c0t011 (NDMP)
2> 4mm @ 0.0.2 ==> c0t012 (NDMP)
3> 4mm @ 0.0.3 ==> c0t013 (NDMP)
4> 4mm @ 0.0.4 ==> c0t014 (NDMP)
5> 4mm @ 0.0.5 ==> c0t015 (NDMP)
6> 4mm @ 0.0.6 ==> c0t016 (NDMP)

These are all the drives that this jukebox has reported.

To change the drive model(s) or configure them as shared
or NDMP drives,

you need to bypass auto-configure. Bypass auto-configure?
(yes / no) [no] yes

Is (any path of) any drive intended for NDMP use? (yes
/ no) [no] yes

Is any drive going to have more than one path defined?
(yes / no) [no] no

Please enter the device path information in one of the
following formats:

/dev/rmt/lcbn --for local path or

host:device-path --for remote node or NDMP device(s)

or
```

```
host:drive-letter:directory path --for Windows disk file
```

After you have entered a device path, you will be prompted for an NDMP

user name for that path's host. If this device path is not an NDMP device,

press the enter key to advance to the next device path. For NDMP devices,

you need to enter the user name and password the first time we encounter

that NDMP host. Pressing the enter key for the NDMP user name for any

subsequent device path on the same host will set the user name and password

to those defined the first time. You will not be prompted for the password

in such a case.

```
Drive 1, element 1, system device name = c0t011,
```

```
local bus, target, lun value = 0.0.1,
```

```

## Tape drive buffer sizes

Table 7 on page 129 lists the buffer size settings, called block size in NetWorker documentation, for different types of tape drives. You must set the `bufsz` parameter on VNX by using the appropriate value for your tape drive type. [Configure Data Movers on page 46](#) explains how to set the `bufsz` parameter.

**Table 7. Tape drive buffer size settings**

## Fujitsu-Siemens NetWorker

[EMC NetWorker on page 124](#) offers more information.

---

## Configure HP OpenView Storage Data Protector

The tasks to configure HP OpenView Storage Data Protector software (based on version 5.5) are:

1. [Import the NDMP server host on page 132](#)
2. [Create a media pool on page 133](#)
3. [Configure the tape library unit on page 133](#)

---

### Import the NDMP server host

1. In the **HP OpenView Storage Data Protector Manager**, switch to the clients context.
2. In the **Scoping** pane, expand **Data Protector Cell**.
3. Right-click **Clients**, and select **Import Client**.
4. In the **Import Client** window, type the name of the NDMP-Host Data Mover you want to import, and select **NDMP server**.

---

**Note:** The HP Data Protector server should be able to map this Data Mover name to an IP address.

---

5. Click **Next**.
6. In the **Import NDMP Host** window, type the specific import parameters:
  - **NDMP Type:** Select VNX.
  - **Port:** Type 10000
  - **Username:** Use the same username that you used in [Assign a username and a password to a Data Mover on page 56](#).
  - **Password:** Use the same password that you used for the NDMP-Host Data Mover in [Assign a username and a password to a Data Mover on page 56](#).
7. Click **Finish** to import the NDMP-Host Data Mover.

---

## Create a media pool

Data Protector requires that the NDMP devices have dedicated media pools. Before you create an NDMP device, create a dedicated media pool to be used exclusively with this device as follows:

1. From the **Devices and Media** context, use the **Add Media Pool** wizard to create a media pool. Online help offers more information.

---

**Note:** Data Protector Free pools are not supported with the Data Protector NDMP integration.

---

2. Format the media by browsing for the specific device, media pool, or library slot in the **Devices and Media** context.

---

**Note:** Devices are automatically formatted when you select them for backup if the loose media allocation policy is defined for the media pool or the global variable `InitOnLoosePolicy` is set to 1. The value is 0.

---

3. Right-click the device, media pool, or library slot and select **Format**. Online help offers more information.

---

## Configure the tape library unit

If your TLU robot is attached to the NDMP-Host Data Mover, you need to configure the TLU for the Data Mover. Use this procedure to configure a TLU whose robot is attached to the NDMP-Host Data Mover. If you are not using a TLU, then configure a stand-alone drive:

1. Switch to the **Devices and Media** context.
2. Expand **Environment**, right-click **Devices**, and select **Add Device**. The **Add Device** wizard appears.
3. Specify the device name and then click **Next**. You can type the description as follows:
  - **Device Type:** Select SCSI II Library.

---

**Note:** To configure a stand-alone drive, select Standalone.

---

- **Interface Type:** Select NDMP-VNX.
- **Client:** Select the NDMP client system running the Data Protector software.
- **NDMP server:** Select the Data Mover where the robotic device is attached.

4. Follow the wizard and type the library SCSI ID for the robotic device attached to the Data Mover.

The SCSI address has this format:

```
<SCSI_controller> <SCSI_ID> <SCSI_LUN>
```

where:

```
<SCSI_controller> = chain number of the controller
```

```
<SCSI_ID> = SCSI ID (target) of the controller
```

```
<SCSI_LUN> = logical unit number (LUN) of the controller
```

Example:

```
c1t0l0
```

[Set up the TLU on page 53](#) provides more information.

5. Specify the slots you want to use with the Data Mover and click **Next**.
6. Select the media type used in the library and click **Next**.
7. Click **Finish** to configure the device. Click **Yes** to configure the drives in the library.
8. Specify the drive name. You also have the option of typing the description for the drive. Click **Next**.
9. Follow the wizard and type the information about the drive's SCSI address.

The SCSI address has this format:

```
<SCSI_controller> <SCSI_ID> <SCSI_LUN>
```

where:

```
<SCSI_controller> = chain number of the controller
```

```
<SCSI_ID> = SCSI ID (target) of the controller
```

```
<SCSI_LUN> = LUN of the controller
```

Example:

```
c1t0l0
```

[Set up the TLU on page 53](#) provides more information.

---

**Note:** Do not change the drive index number.

---

10. Click **Next**, and then specify the media and media pools information.
11. Click **Yes** to create another drive or **No** to finish creating drives for the library.  
The *HP OpenView Storage Data Protector Administrator's Guide* and online help provide more information on creating a drive.

## IBM Tivoli Storage Manager

These restrictions apply when performing NDMP backups with VNX and IBM Tivoli Storage Manager:

- ◆ You must use a Windows Tivoli Storage Manager client to browse an NDMP backup. Windows is the only client type that allows you to perform a file-by-file restore with Tivoli Storage Manager.
- ◆ Supports only two-way backup.
- ◆ Does not support environment variables.
- ◆ You cannot run concurrent NDMP backups on a Data Mover where the target backup devices are DLT drives on the same SCSI bus, and are attached to an IBM 2108 SAN Data Gateway (all models) or an ADIC Pathlight 5000. Tivoli Storage Manager supports concurrent NDMP backups of Data Movers to direct SCSI-attached DLT drives.

## Configure IBM Tivoli Storage Manager

This procedure is based on IBM Tivoli Storage Manager version 5.2, 5.3, or 5.4 and requires you to log in to the SUN TSM Admin client before you begin.

Perform the following steps to configure IBM Tivoli Storage Manager:

1. To define a library, use the command syntax:

```
$ define library <library_name> libtype=scsi shared=no
```

where:

*<library\_name>* = name you want to assign the library

Example:

To define a library, type:

```
$ define library ndmplib libtype=scsi shared=no
```

2. To define the device class, use the command syntax:

```
$ define devclass <device_class> library=<library_name> devtype
= nas mountretention=0 estcapacity= <media_capacity>
```

where:

*<device\_class>* = name you want to assign the device class.

*<library\_name>* = library name you assigned in step 1.

*<media\_capacity>* = estimated capacity of the media. This value depends upon a tape's capacity.

---

Note: For NDMP operations, the mountretention value must be 0.

---

Example:

To define the device class, type:

```
$ define devclass nasclass library=ndmplib devtype=nas mountretention=0
estcapacity=70g
```

- To define a tape storage pool, use this command syntax:

```
$ define stgpool <storage_pool> <device_class> maxscratch=30
dataformat=celerradump
```

where:

*<storage\_pool>* = name you want to assign the storage pool.

*<device\_class>* = device class name you assigned in step 2.

Example:

To define a tape storage pool, type:

```
$ define stgpool naspool nasclass maxscratch=30 dataformat=celerradump
```

- To create a policy domain for the NDMP-Host Data Mover, from the Tivoli Storage Manager software, use the command syntax:

```
$ define domain <policy_domain> description='<policy_description>'
```

where:

*<policy\_domain>* = name you want to assign the policy domain.

*<policy\_description>* = user-defined description of the NDMP policy.

Example:

To create a policy domain for the NDMP-Host Data Mover, type:

```
$ define domain nasdomain description='policy domain for NDMP-Host Data Mover'
```

- To create a policy set in the domain you created in step 4, use the command syntax:

```
$ define policyset <policy_domain> <policy_set>
```

where:

*<policy\_domain>* = policy domain you assigned in step 4.

*<policy\_set>* = name you want to assign the policy set.

Example:

To create a policy set, type:

```
$ define policyset nasdomain naspolicy
```

6. To define a management class, use this command syntax:

```
$ define mgmtclass <policy_domain> <policy_set> <management_class>
```

where:

<policy\_domain> = policy domain you assigned in step 4.

<policy\_set> = policy set name you assigned in step 5.

<management\_class> = management class name you specify.

Example:

To define a management class, type:

```
$ define mgmtclass nasdomain naspolicy nasmgtclass
```

7. To assign the management class as the default for the policy set, use this command syntax:

```
$ assign defmgmtclass <policy_domain> <policy_set> <management_class>
```

where:

<policy\_domain> = policy domain you assigned in step 4.

<policy\_set> = policy set you assigned in step 5.

<management\_class> = name you want to assign the management class.

Example:

To assign the management class as the default for the policy set, type:

```
$ assign defmgmtclass nasdomain naspolicy nasmgtclass
```

8. To define a backup pool and set the allowable TOC size, use this command syntax:

```
$ define volume backuppool <pool_name> f=<size>
```

where:

<pool\_name> = name of the backup pool.

<size> = maximum size in MB of a backup's TOC.

Example:

To define a backup pool and set the allowable TOC size, type:

```
$ define volume backuppool bkpool f=1000
```

9. To define a backup policy group in the default management class, use this command syntax:

```
$ define copygroup <policy_domain> <policy_set> <management_class>  
destination=<storage_pool> verexits=<number_of_backup_versions>  
tocdestination=<TOC_storage_pool>
```

where:

<policy\_domain> = domain policy you assigned in step 4.

*<policy\_set>* = policy set you assigned in step 5.

*<management\_class>* = management class you assigned in step 6.

*<storage\_pool>* = storage pool you assigned in step 3.

*<number\_of\_backup\_revisions>* = the number of backup versions you want to retain in your table of contents (index).

*<TOC\_storage\_pool>* = TOC destination.

---

**Note:** Ensure that the destination for the copy group is assigned the appropriate backup format (celerradump). Step 3 provides more information.

---

Example:

To define a backup policy group in the default management class, type:

```
$ define copygroup nasdomain naspolicy nasmgmtclass destination=naspool verexits=10
tocdestination=backuppool
```

10. To activate the policy set, use this command syntax:

```
$ activate policyset <policy_domain> <policy_set>
```

where:

*<policy\_domain>* = policy domain you assigned in step 4.

*<policy\_set>* = policy set you assigned in step 5.

Example:

To activate the policy set, type:

```
$ activate policyset nasdomain naspolicy
```

11. To register the Data Mover with the Tivoli Storage Manager server, use this command syntax:

```
$ register node <movername> <password> domain=<policy_domain>
type=nas
```

where:

*<movername>* = name of the Data Mover you want to register. This server must be accessible from the Tivoli Storage Manager client for your setup to work properly.

*<password>* = Data Mover password you assigned in [Assign a username and a password to a Data Mover on page 56](#).

*<policy\_domain>* = policy domain you assigned in step 5.

Example:

To register the Data Mover with the Tivoli Storage Manager server, type:

```
$ register node server_2 admin domain=nasdomain type=nas
```

12. To define each NDMP-Host Data Mover, use this command syntax:

```
$ define datamover <movername> type=nas hladdress=<movername_IP_address>
lladdress=10000 userid=user_name password=<password>
dataformat=celerradump
```

where:

*<movername>* = Data Mover name you registered with the Tivoli Storage Manager server in step 11.

---

**Note:** The Data Mover name must match the name you used in the previous step to register the Data Mover with the Tivoli Storage Manager server.

---

*<movername\_IP\_address>* = Data Mover IP address.

**lladdress** = NDMP port number, which must be 10000.

**userid** = NDMP username you assigned in [Assign a username and a password to a Data Mover on page 56](#).

*<password>* = Data Mover password you assigned in [Assign a username and a password to a Data Mover on page 56](#).

---

**Note:** You must specify 10000 as the lladdress.

---

Example:

To define each NDMP-Host Data Mover, type:

```
$ define datamover server_2 type=nas hladdress=192.0.0.2 lladdress=10000
userid=user_name password=admin dataformat=celerradump
```

13. To define a path to a library, use this command syntax:

```
$ define path <movername> <library_name> srctype=datamover desttype
=library device=<device_name>
```

where:

*<movername>* = name of the Data Mover connected to the TLU.

*<library\_name>* = library name you assigned in step 1.

*<device\_name>* = TLU device name used by VNX. This name is determined by the SCSI controller, SCSI ID, and SCSI LUN. [Set up the TLU on page 53](#) explains how to obtain a device name.

Example:

To define a path to a library, type:

```
$ define path server_2 ndmplib srctype=datamover desttype=library device=c2t010
```

14. To show slots to reveal the element numbers you require in the next step, use this command syntax:

```
$ show slots <library_name>
```

where:

<library\_name> = library name you assigned in step 1.

Example:

To show slots to reveal the element numbers, type:

```
$ show slots ndmplib
```

15. To define the tape drives for NDMP operations and the paths to those drives, use this command syntax:

```
$ define drive <library_name> <drive_name> element=<element_number>
```

where:

<library\_name> = library unit name you assigned in step 1.

<drive\_name> = drive name, which can be any name you want to assign.

<element\_number> = element addresses, which step 14 revealed.

Examples:

To define the tape drives for NDMP operations and the paths to those drives, type:

```
$ define drive ndmplib eisen1 element=128
```

```
$ define drive ndmplib eisen2 element=129
```

---

Note: Repeat this step for each drive in your library.

---

16. To define a path for the drive, use this command syntax:

```
$ define path <movername> <drive_name> srctype=datamover desttype=  
=drive library=<library_name> device=<device_name>
```

where:

<movername> = name of the Data Mover connected to the TLU.

<drive\_name> = drive name you assigned in step 15.

<library\_name> = library name you assigned in step 1.

<device\_name> = device name used by VNX. [Set up the TLU on page 53](#) provides more information on locating device names.

Examples:

To define a path for the drive, type:

```
$ define path server_2 eisen1 srctype=datamover desttype=drive library=ndmplib  
device=c2t210
```

```
$ define path server_2 eisen2 srctype=datamover desttype=drive library=ndmplib  
device=c2t310
```

---

## Configure Syncsort Backup Express

Syncsort Backup Express configuration procedures are based on using VNX and Syncsort Backup Express version 2.3:

1. [Configure the Data Mover on page 141](#)
2. [Configure the libraries attached to the Data Mover on page 141](#)
3. [Run an NDMP backup of a Data Mover on page 142](#)

---

## Configure the Data Mover

1. From the **Syncsort Backup Express** home page, select **Configure** ► **Enterprise**.
2. Select the enterprise, and then select the Node Group to which you want to add the Data Mover. Click **Add Node**.
3. When the page refreshes, type the **Logical Node Name**, **Resolvable Node Name** or **IP address**, **Client node**, **Port 10000**, **User Name**, and the **Password** that you created for the NDMP-Host Data Mover.
4. Click **TEST** to verify that the correct authentication with the Data Mover, and click **Apply**.

---

## Configure the libraries attached to the Data Mover

1. Start the **Syncsort Backup Express Device Configuration Wizard** and provide the login information. Click **Next**.
2. Select the Data Mover to which the TLU is attached and click **Next**. When the system finishes querying the Data Mover for the list of libraries (status = Done), click **Next**.
3. Select the library you want to configure. Click **Next**. The **Add Jukebox** window appears.
4. Configure the requested parameters and click **Next**.
5. To configure the tape drives, select **Add Device**. Select the controller Path and specify the Device Bay number and Device name. Click **OK**.
6. Repeat step 5 for each tape drive you want to configure.
7. Click **Exit**.

---

## Run an NDMP backup of a Data Mover

1. From the **Syncsort Backup Express** home page, select **BACKUP** and click **NDMP**. The **NDMP Backup** window appears.
2. Select the Enterprise. From the **Node Group** category select the Data Mover you want to back up. (This is the Data Mover you configured in [Configure Data Movers on page 46.](#))
3. From the **Backup** menu, select **Define Source Options**. The **Define Source Options** window appears.
4. Set the desired environment variables for the selected backup job:

---

Note: Syncsort Backup Express offers two ways to enable the EMC NVB feature:

- Set the environment variable VBB=yes for the specific backup job.
- Select vbb as the backup type for the Data Mover.

This step shows how to enable VBB by using both methods, and explains the reasons for using each. [Backup/restore with NVB on page 29](#) provides more details on the NVB feature.

---

- a. Use this procedure to set the desired environment variables, including the NVB variable, for the selected backup job.

In the Additional NDMP Environment field of the **Define Source Options** window of the selected backup job, type the desired NDMP environment variables (comma separated).

Example:

```
SNAPSURE=y, VBB=y, HIST=y
```

It is recommended to enable VBB by using the VBB variable (as shown above, with the other variables for the backup job) because specifying the backup method at the backup-job level makes it easier to manage different backup methods on the same Data Mover.

- b. Optionally, you can enable NVB at the Data Mover level, as follows: From the Syncsort Backup Express home page, select **Configure** and click **Enterprise**. Select the Enterprise, Node Group, and Data Mover name that you want to back up. Next, from the **Backup Type** list, select **vbb**. At this point, every NDMP backup job run with the selected Data Mover will be performed by using the NVB method.

Use of this method makes it difficult to troubleshoot a situation where a VBB type is set at the Data Mover level, and a non-VBB-supported configuration is specified when defining a specific backup job. (Examples of a nonsupported configuration include backing up a subdirectory of the file system, or backing up a file system that is not read-only.)

5. Click **OK**. Select **File** and click **Save Job**.
6. Select **BACKUP** and click **Run**.

---

## Configure Symantec NetBackup

The procedures for configuring Symantec NetBackup are based on Symantec NetBackup versions 5.0, 5.1, 6.0, and 6.5. They include steps for configuring backup devices in Media Manager, the Symantec NetBackup graphical user interface. The procedures for configuring devices for Media Manager are performed from the NetBackup Administration Console. When configuring Symantec NetBackup for NDMP operations, you must:

1. Configure the system devices.
2. Specify the information that Media Manager, the Symantec NetBackup graphical user interface, requires to control the devices.

Each procedure highlights some of the VNX-specific information, but does not cover the configuration in detail. You cannot use the Device Configuration wizard to configure devices for NDMP. You can use the Device Monitor to verify that the devices were set up properly. A successfully configured device is in an “Up” state.

Also, ensure that the HIST environmental variable is enabled before performing a backup, and enable DAR before a restore to make DAR available for file recovery.

To configure Symantec NetBackup:

1. [Enable host access to a Data Mover on page 143](#)
2. [Configure a robot on page 148](#)
3. [Add a robot on page 150](#)
4. [Update the volume database on page 152](#)
5. [Add a drive on page 152](#)
6. [Add a storage unit on page 153](#)
7. [Create a backup policy on page 153](#)
8. [Specify a backup type on page 154](#)

---

## Enable host access to a Data Mover

To perform NDMP backups, NetBackup must have access to the Data Mover as the NDMP host. To authorize host access to the Data Mover, perform the following procedure from the NetBackup Administration Console on your NetBackup for NDMP master server.

You can enable host access to the Data Mover by:

- ♦ [Using the CLI on page 144](#)

- ◆ [Using the NetBackup Administration Console on page 145](#)

---

Note: Use the NetBackup Administration console for versions 6.0 and later.

---

## Using the CLI

Perform the following steps to enable host access to a Data Mover using the CLI:

1. To enable host access to a Data Mover, use the command syntax:

```
set_ndmp_attr -insert -auth <movername> user_name
```

where:

*<movername>* = customer-assigned name for the NDMP-Host Data Mover connected to the TLU. Symantec NetBackup NDMP accesses a Data Mover by its NIS, DNS (Domain Name Server), or /etc/hosts name.

*user\_name* = username under which Symantec NetBackup NDMP accesses the Data Mover.

For Windows NT/2000 systems, the `set_ndmp_attr` command is located in the `<install_path>\Volmgr\bin` directory. By default, the location is `C:\Program Files\Veritas\Volmgr\bin`.

For a UNIX system, the command is located in the `/usr/opensv/volmgr/bin/` directory.

Example:

On Windows NT/2000, where the Data Mover name is `server_2`:

```
<install_path>\Volmgr\bin\set_ndmp_attr -insert -auth server_2 user_name
```

On UNIX, where the Data Mover name is `server_2`:

```
/usr/opensv/volmgr/bin/set_ndmp_attr -insert -auth server_2 user_name
```

Output:

```
Password: password
Re-enter Password: *****
Password for host "server_2" user "user_name" Re-enter Password
forhost "server_2" user "user_name":
Re-enter Password for host "server_2" user "user_name":
Inserted host "server_2"
```

where:

Password = the same password set for the NDMP-Host Data Mover. [Assign a username and a password to a Data Mover on page 56](#) provides more information.

---

Note: VNX accesses a Data Mover by its internal name (movername), such as `server_2`, but this field can be anything the customer assigns.

---

- If you are performing a Data Mover-to-Data Mover three-way backup, repeat step 1 for the Data Mover without an attached tape drive. After this step is completed, the Data Mover is listed in the GUI under NDMP hosts.

### Using the NetBackup Administration Console

- Start the **NetBackup Administration Console** for the NDMP server:
  - In a Windows environment: From the **Start** menu, select **Programs > Symantec NetBackup > NetBackup Administration Console**.
  - In a UNIX environment, type:
 

```
/usr/opensv/netbackup/bin/jnbSA &
```
- From **Media and Device Management** in the left pane, select **Credentials** and click **NDMP Hosts**.
- From the **Actions** menu, select **New** and click **NDMP Host**. The **NDMP host name** dialog box appears.

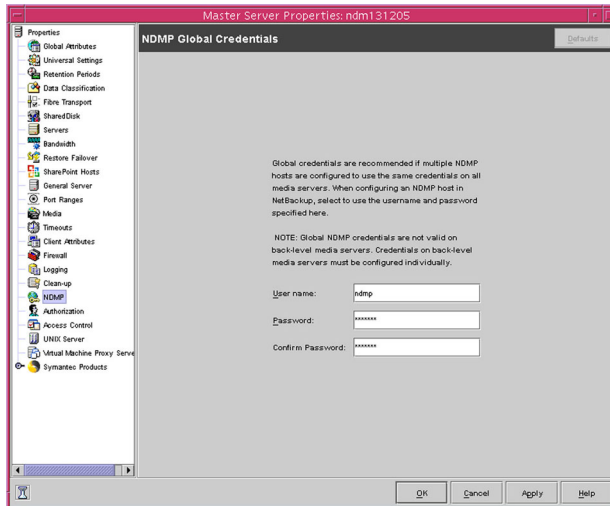

- Type the name of the NDMP server to back up and click **OK**. The **New NDMP Host** dialog box appears.

---

Note: The NDMP host name is case-sensitive.

---

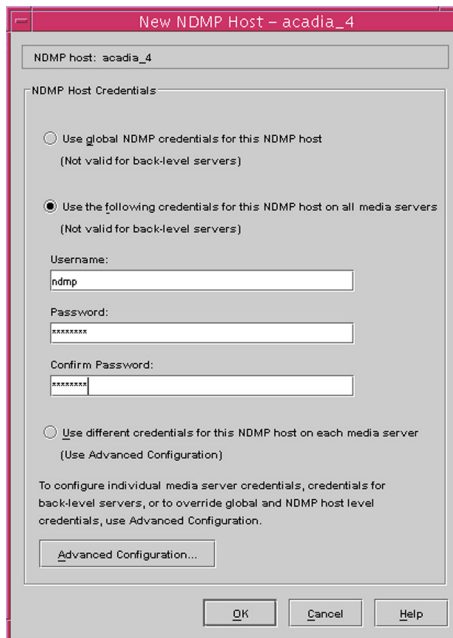

- Under **NDMP Host Credentials**, select the appropriate option from the list given below and type the username and password that NetBackup uses to access the NDMP host:
  - For the **Use Global NDMP credentials for this NDMP host** option:
    - Click **Host Properties** and select **Master Server**.
    - Double-click the **Master Server** option from the right pane. The **Properties** dialog box appears.
    - From **Properties**, select **NDMP**. The **NDMP Global Credentials** dialog box appears.
    - In the **NDMP Global Credentials** dialog box, type the username and password in the **Username**, **Password**, and **Confirm password** fields, respectively. Use the same username and password that NetBackup uses to access the NDMP server.
    - Click **Apply** and then click **OK**.

- For the **Use the following credentials for this NDMP host on all media servers** option:
  - a. Type the username and password in the **Username**, **Password**, and **Confirm password** fields, respectively. Use the same username and password that NetBackup uses to access the NDMP server.

Note: The user must have permission to run NDMP commands.

- b. Click **OK**.

- For the **Use the following credentials for this NDMP host on all media servers** option:
  - a. Click **Advanced Configuration**. The **Advanced NDMP Credentials** dialog box appears.
  - b. Click **Add** to open the **Add Credentials** dialog box.
  - c. Type the username and password in the **Username**, **Password**, and **Confirm password** fields, respectively. Use the same username and password that NetBackup uses to access the NDMP server.

---

Note: The user must have permission to run NDMP commands.

---

- d. Click **OK**.

6. Verify access between the NDMP host and the NDMP client by using this command syntax:

```
tpautoconf -verify <movename>
```

where:

<movename> = name of the Data Mover

Example:

Windows: <install\_path> \Volmgr\bin\tpautoconf -verify server\_2

UNIX: /usr/opensv/volmgr/bin/ tpautoconf -verify server\_2

Output:

```
# ./tpautoconf -verify server_2
Connecting to host "server_2" as user "ndmp"...
Waiting for connect notification message...
Opening session--attempting with NDMP protocol version 4...
Opening session--successful with NDMP protocol version 4
  host supports TEXT authentication
  host supports MD5 authentication
Getting MD5 challenge from host...
Logging in using MD5 method...
Host info is:
  host name "server_2"
  os type "DartOS"
  os version "EMC Celerra File Server.T.5.6.45.4"
  host id "abc1997"
Login was successful
Host supports LOCAL backup/restore
Host supports 3-way backup/restore
```

Repeat this procedure for each NDMP host that NetBackup backs up, and also for a Data Mover-to-Data Mover three-way backup, for the Data Mover without an attached tape drive. After this step is completed, the Data Mover is listed in the GUI under NDMP hosts.

## Configure a robot

 **CAUTION** Do not perform this step for versions 6.0 and later.

Specify the data for the robotic control that is attached to the NDMP-Host Data Mover. For NDMP client-attached robotic control information, consult the NetBackup documentation.

When configuring a robot that attaches directly to the NDMP-Host Data Mover, you must specify these information:

- ◆ Device name of the robot
- ◆ SCSI controller number for the robot
- ◆ SCSI ID for the robot
- ◆ SCSI LUN for the robot

Perform the following steps to configure a robot:

1. To specify the robotic control, use this command syntax:

```
$ set_ndmp_attr -insert -robot <movername> <device_name> <SCSI_
controller> <SCSI_ID> <SCSI_LUN>
```

where:

<movername> = name of the NDMP-Host Data Mover

<device\_name> = robotic device name ([Set up the TLU on page 53](#) explains how to obtain a device name)

<SCSI\_controller> = controller number

<SCSI\_ID> = SCSI ID for the robotic control

<SCSI\_LUN> = LUN for the robotic control

Windows example:

```
<install_path> \Volmgr\bin\set_ndmp_attr -insert -robot server_2 c1t010 1 0 0
```

UNIX example:

```
/usr/openv/volmgr/bin/set_ndmp_attr -insert -robot server_2 c1t010 1 0 0
```

Output:

```
Inserted robot host "server_2:c1t010" device "1"
```

**Note:** If you make an error configuring the robot, delete the configuration by using this command syntax:

```
$ set_ndmp_attr -delete -robot <movername> <devicename> <SCSI
_controller> <SCSI_Id> <SCSI_Lun>
```

Example:

```
$ set_ndmp_attr -delete -robot server_2 c1t010
```

Output:

```
Deleted robot host "server_2" device "c1t010"
```

2. To verify that the authentication record is created and view the record for accuracy, type:

```
set_ndmp_attr -list
```

Windows example:

```
<install_path> \Volmgr\bin\set_ndmp_attr -list
```

UNIX example:

```
/usr/openv/volmgr/bin/set_ndmp_attr -list
```

Output:

```
Record Type: Authentication
NDMP server: server_2
Username: user_name
Password: <registered>
Record Type: Robotic Information
NDMP server: server_2
Device: c1t010
Controller: 1
SCSI Id: 0
SCSI Lun: 0
```

3. To verify access between the NDMP host and the NDMP client, use this command syntax:

```
set_ndmp_attr -verify <movername>
```

where:

<movername> = name of the Data Mover

Windows example:

```
<install_path> \Volmgr\bin\set_ndmp_attr -verify server_2
```

UNIX example:

```
# /usr/opensv/volmgr/bin/set_ndmp_attr -verify server_2
```

Output:

```
Connecting to host "server_2" as user "user_name"...
Waiting for connect notification message...
Opening session with NDMP protocol version 2..
Host info is:
host name "Server"
os type "SNAS"
os version "5.4"
host id "abc1997"
Logging in using TEXT method...
Login was successful
```

## Add a robot

Use these steps to add a robot from the **NetBackup Administration Console**, for NDMP master server:

Note: For NetBackup versions prior to 6.0, follow the steps in [Configure a robot on page 148](#) to add a robot.

1. From **Media and Service Management** in the left pane, click **Devices**.
2. From the **Actions** menu, select **New** and click **Robot**. The **Add a New Robot** dialog box appears.
3. In the **Add Robot** dialog box, type the appropriate information in the fields listed below (use the online help or Symantec documentation for assistance):
  - **Media Manager host:** Specify the host that manages the EMM database (by default, this is the NetBackup master server).
  - **Device host:** Use the drop-down list to select the NetBackup media server.
  - **Robot type:** Specify the robot type.
  - **Robot name:** Specify the robot name.
  - **Robot control:** Select the robot control that is attached to an NDMP host option.
  - **Robot device path:** Type the device name of the robot by using this command syntax:

```
<SCSI_controller> <SCSI_Id> <SCSI_Lun>
```

where:

```
<SCSI_controller> = chain number of the controller
```

<SCSI\_Id> = SCSI ID of the controller, also called target

<SCSI\_Lun> = LUN of the controller

Example:

c1t010

Note: Do not include the NDMP host name as part of the device path. [Set up the TLU on page 53](#) provides more information on determining the robot device name.

- **NDMP host name:** Type the name of the NDMP host to which the robot is attached.
- **Bus, Target, and LUN:** Use the values that you used specified for the robot device path. For example, use 1, 0, and 0 for bus, target, and LUN, respectively, from the previous example. The bus, target, and LUN values are 0 by default.

4. Click **OK** in the **Add New Robot** dialog box. A pop-up window prompts you to restart the device manager service.
5. Click **No** to continue configuring other devices before restarting the device manager.

**CAUTION** Restarting this service can abort backups, archives, or restores in progress.

---

### Update the volume database

1. Insert the volumes into the robotic library.
2. Under **Media and Device Management** in the **NetBackup Administration Console**, click **Media > Robots**.
3. Select the robotic library where you inserted the volumes.
4. Click **Actions > Inventory Robot**.
5. In the **Inventory Type** section, select **Update Volume Configuration**.
6. Click **Start** to start the inventory and update the database.

---

### Add a drive

1. Under **Media and Device Management** in the **NetBackup Administration Console**, click **Devices**.
2. From the **Actions** menu, select **New > New Drive**. The **Add Drive** dialog box appears.
3. Complete the dialog box fields. Consult online help for more information.

For the **Device name** field, use this syntax for a drive directly attached to the NDMP-Host Data Mover:

```
<movername>:<device_file>
```

where:

```
<movername> = name of the Data Mover
```

```
<device_file> = name of the file for the drive
```

Example:

`server_2:c1t110`

4. When you complete the dialog box fields, click **OK**. A message appears asking whether you want to restart the Media Manager.
5. Click **Yes**.

---

## Add a storage unit

1. In **NetBackup Management** in the **NetBackup Administration Console**, click **Storage Units**.
2. From the **Action** menu, select **New ► New Storage Unit**. The **Add New Storage Unit** dialog box appears.
3. In **Storage Unit Type**, click the arrow and select **NDMP** from the list.
4. Type the appropriate information in the dialog box fields.

---

**Note:** Consult online help for more information.

---

In NDMP host, type the name of the Data Mover.

Example:

`server_2`

5. When you complete, click **OK**.

---

## Create a backup policy

1. Specify these attributes:
  - **Policy Type:** NDMP
  - **Policy Storage Unit:** Name of the storage unit if the NDMP host has more than one
  - **For a three-way backup:** Storage unit that you defined for the NDMP host with an attached tape drive
2. Configure the client or clients as follows:
  - **Hostname:** Name of the NDMP-Host Data Mover
  - **Hardware and operating system:** NDMP NDMP
3. Configure the files so the file list contains directories that reflect the directories on the NDMP Host. NDMP does not support these file list capabilities:

- Wildcards in pathnames
  - Individual filenames
  - Exclude list
4. Verify the configuration by running a backup policy.

---

## Specify a backup type

By default, Symantec uses the dump backup type. You can change the backup type from dump to tar or vbb by specifying a variable in the backup policy's file list as follows:

1. In the **NetBackup Administration Console**, expand **Master Server > NetBackup Management > Policies**.
2. In the middle pane, double-click the policy you want to edit. The **Change Policy** dialog box appears.
3. Click the **Backup Selections** tab, and select the path or directory where you want to use the vbb backup type.
4. Click **Insert**. The **Insert File** dialog box appears.
5. In Pathname or directive, define the variable by typing:

```
SET type = vbb
```

6. Press **Enter** and click **OK**. The new variable should now appear in the middle pane of the **NetBackup Administration Console**, above the directories or files to which it applies.

---

Note: In the file list, the variable definition must appear before the directories or files to which it applies.

---

*NetBackup for NDMP System Administrator's Guide for UNIX and Windows* provides more information on using variables.

---

## Configure Symantec Backup Exec

Before configuring the NDMP server with the Backup Exec server, ensure that the following has been installed on the Backup Exec server:

- ♦ Windows Servers or Windows XP
- ♦ Backup Exec for Windows Servers

---

Note: While installing Backup Exec, make sure that you select the NDMP option, which is an add-on component.

---

To configure Symantec Backup Exec:

1. [Add the NDMP server to the Backup Exec on page 155](#)
2. [Inventory the newly added TLU on page 156](#)
3. [Create a backup job on page 158](#)
4. [Create a restore job on page 160](#)

---

## Add the NDMP server to the Backup Exec

To configure Backup Exec in order to use the NDMP option, add the NDMP server to Backup Exec. If any storage devices are attached to the NDMP server, the Backup Exec locates them automatically and adds them to the list of devices.

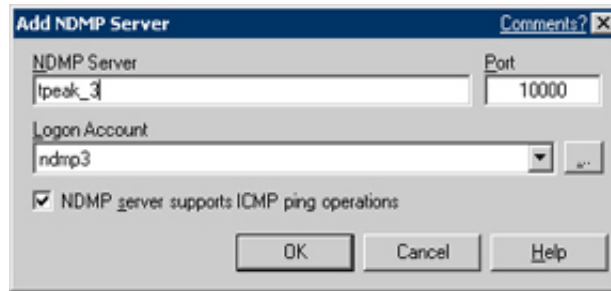

---

Note: Before starting the installation process, edit the host file in the Windows machine that hosts the Backup Exec application to include the IP address and name of the NDMP servers.

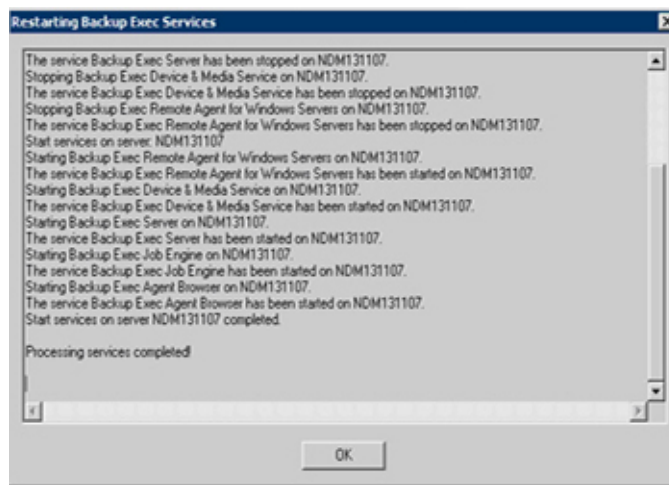

---

To add an NDMP server to Backup Exec:

1. On the navigation bar, click the **Devices** tab.
2. In the task pane, under **NDMP Tasks**, click **Add NDMP Server**. The **Add NDMP Server** dialog box appears.
3. Add the following information in the **Add NDMP Server** dialog box:
  - **NDMP Server:** Type the name of the NDMP server.
  - **Port:** Type the appropriate port number (10000) that is used for communications between the Backup Exec server and the NDMP server.
  - **Logon Account:** Select the appropriate logon account for the NDMP server. To create a new account, click the button next to the **Logon Account** field and then click **New** in the **logon Account Selection** dialog box. Type the same username and password that you used for the NDMP-Host Data Mover.
  - **NDMP server supports ICMP ping operations:** Select this option if the NDMP server supports ICMP ping operations. It ensures that the Backup Exec can use ping to locate the NDMP server ping operations, by default.

4. Click **OK** to add the NDMP server. A warning message box appears. Click **Yes** to restart all the Backup Exec services. The **Backup Exec Services Manager** dialog box appears.
5. Click **Restart all services** to restart the Backup Exec services.
6. Click **OK** when the message **Processing services completed** appears in the **Restarting Backup Exec Services** window.

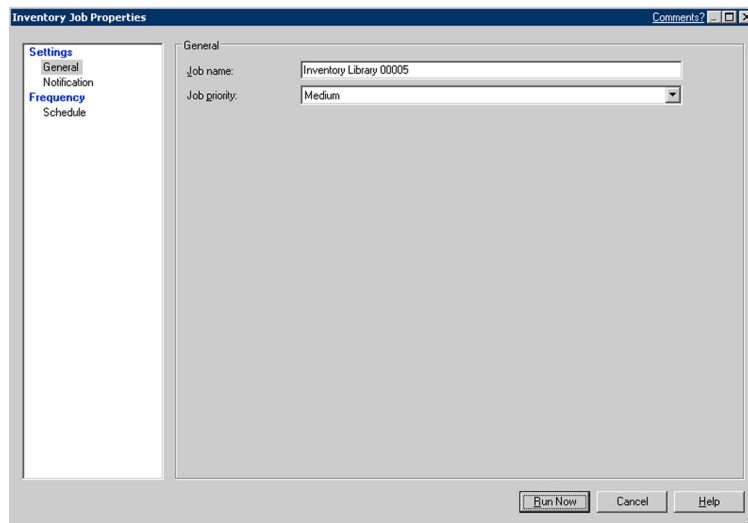

Note: The NDMP server and the storage devices that are directly attached to the Backup Exec appear in the Devices pane. Depending on the number of storage devices, it can take a while for all the devices to be displayed. You need to refresh the GUI to view all the services and devices that are added.

## Inventory the newly added TLU

Following are steps:

1. From the navigation bar, click the **Devices** tab.
2. Select **Robotic Libraries** and right-click the required robot.

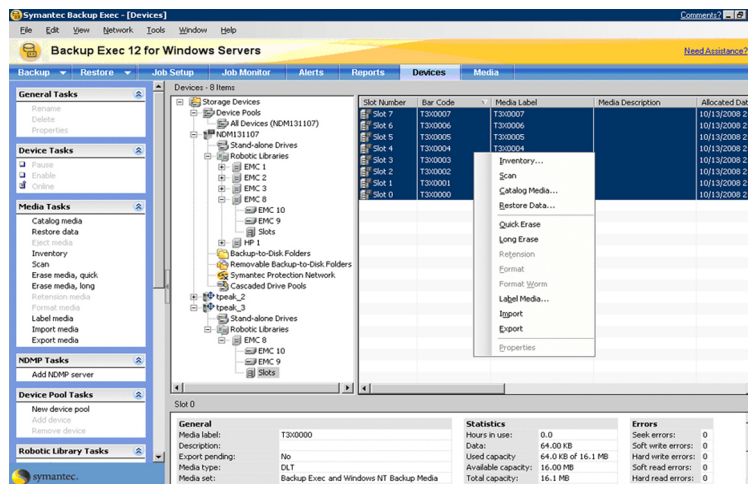

3. Select **Inventory**. The **Inventory Job Properties** dialog box appears.

4. Click **Run Now** to start the inventory. To view and monitor the inventory status, click the **Job Monitor** tab from the navigation bar. The **Job Monitor** window appears.

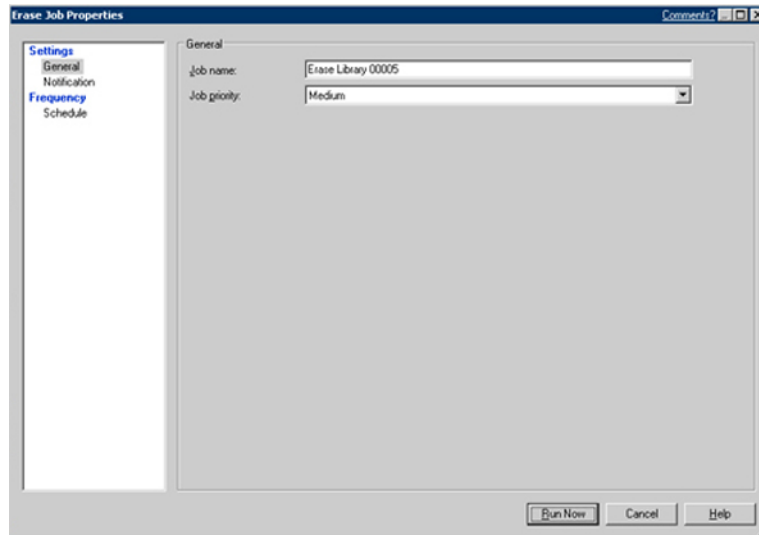

Note: When the inventory job is successfully completed, it is moved to the Job History section in the Job Monitor window.

5. It is recommended to erase and label the tapes. To erase tapes, select **Robotic Library** and click **Slots**. A list of tapes is displayed.
6. Select all the tapes and then right-click to select **Quick Erase**. A warning box appears. Click **OK** to start the Quick Erase process.

Note: To erase all the tapes together, click Yes to All in the Symantec Backup Exec dialog box.

- In the **Erase Job Properties** dialog box, click **Run Now**. To view and monitor the status, click the **Job Monitor** tab on the navigation bar. The **Job Monitor** window appears.

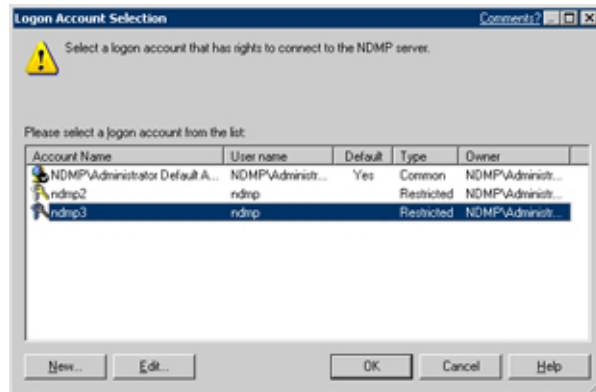

- When the job is completed, the tapes are listed under **Scratch Media Set** and are ready for use. To view the tapes, click the **Media** tab on the navigation bar. From the left panel, select **Media Sets** and then click **Scratch Media set**.
- To label the tapes, select **Robotic Library** and click **Slots**. A list of tapes is displayed.
- Select all the tapes and right-click to select **Label Media**. A warning box appears. Click **OK** to start the labeling process for the first media. Click **OK** to label each media individually. To view and monitor the status of the labeling job, click the **Job Monitor** tab on the navigation bar. The **Job Monitor** window appears.

## Create a backup job

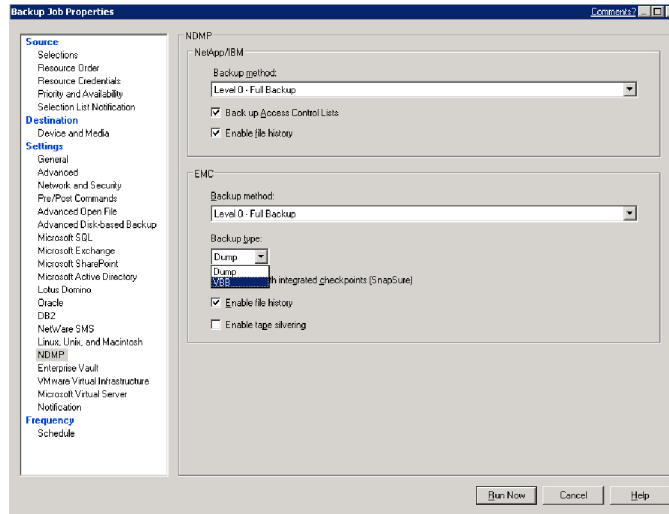

Perform the following steps to create a backup job:

- From the navigation bar, click the **Backup** tab.
- Select **New Backup Job**. The **Backup Job Properties** window appears.
- From the left task panel, select **Source** and click **Selections**.
- To back up a file system, select **All Resources** ► **NDMP Servers** and then select the appropriate NDMP server (where the file system is located). All the file systems to be backed up (except the file systems on which NDMP2D TLUs are built) are displayed. If the **Logon Account Selection** dialog box appears when the NDMP server is selected, select or create the correct account name.

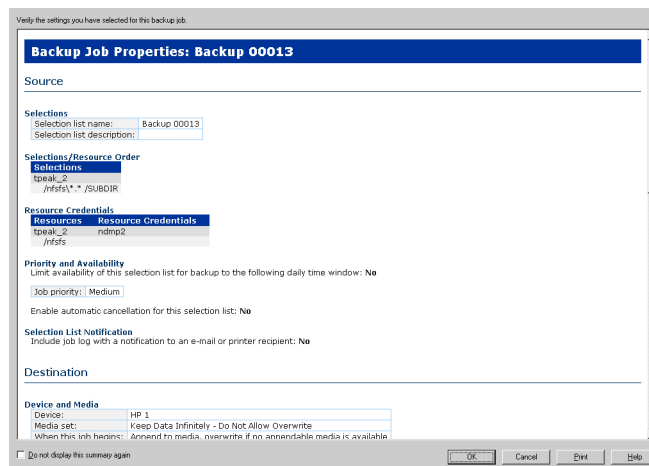

5. To select the required file system for backup, select the checkbox next to it.
6. To select the library to backup the data, select **Devices and Media** from the **Destination** tab.
7. From the **Device** list, select a storage device (for example, the library or one of its drives) where the data needs to be backed up. If you select a storage device that is attached to the Data Mover on which the source file system is mounted it would be a two-way backup, whereas selecting a storage device attached to a remote Data Mover would be a three-way backup.
8. Under **Settings**, click **NDMP** and select the following options:
  - a. From the **Backup method** drop-down list, select the backup method. Level 0 is for full backup, whereas levels 1 through 9 are intended for incremental backups.
  - b. From the **Backup type** drop-down list, select **Dump** or **VBB**.
  - c. Select the checkbox next to the **Backup with integrated checkpoints (VNX SnapSure)** option. This option automatically creates a checkpoint for the file system that is to be backed up.

## Configure your Backup Software

9. Click **Run Now**. A confirmation window appears. Click **OK** to start the backup operation.

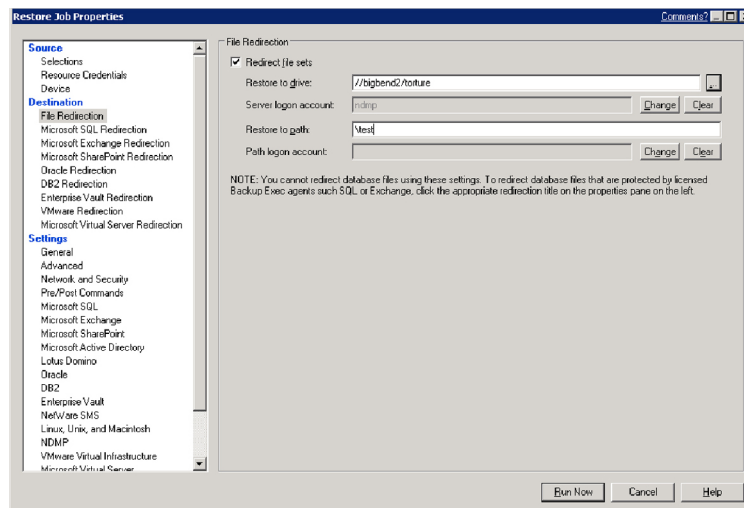

## Create a restore job

Perform the following steps to create a restore job:

1. From the **Restore** tab, click **New Restore Job**. The **Restore Job Properties** window appears.
2. Select **Source** and click **Selections**. The files that are to be restored from their respective NDMP servers are now available.
3. Under **All Resources**, select the appropriate NDMP server to restore files from a backup image. A list of all datasets (file systems and directories) that were previously backed up is displayed.

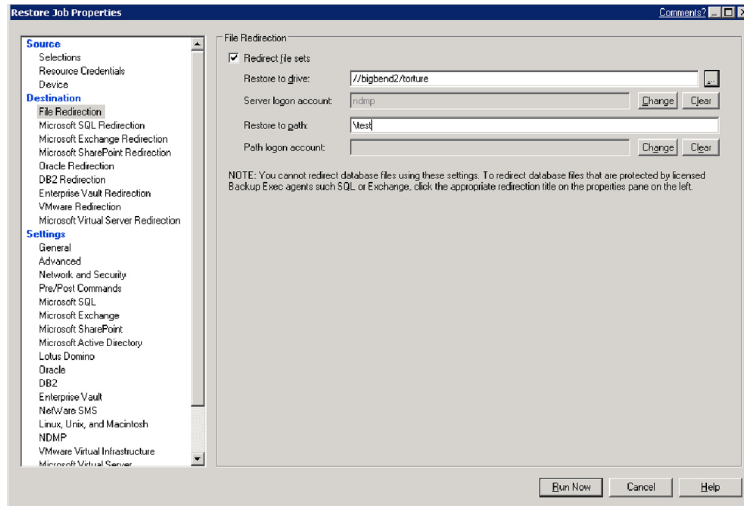

4. Click the required dataset and then select the checkbox next to the required backup image to perform a full restore. You can expand the backup image to select the required files and directories in order to perform a partial restore.
5. Under **Source**, click **Device** and then select the storage device (the library or one of its drives) from where the data needs to be restored.
6. To enable an out-of-place restore, under **Destination**, select **File Redirection** and then select the checkbox next to **Redirect file sets**. In file redirection, the original data is not replaced by the restored data. If the **File Redirection** option is not selected, an In-place restore takes place.

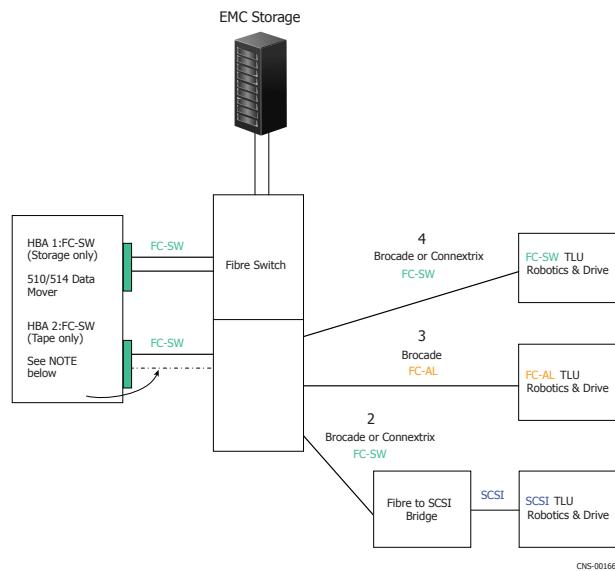

7. In the **Restore to drive** field, specify the NDMP server and the file system by clicking the button next to it. You can also type the drive name.
8. In the **Restore to path** field, specify the out-of-place location within the target file system.
9. Under **Settings**, click **NDMP** and select the checkbox next to the **Enable Direct Access Recovery** option. This option is selected by default to allow the direct access recovery of selected files and directories without restoring the backup image as a whole.
10. Click **Run Now**. A confirmation window appears. Click **OK** to start the restore operation.

## Configure your Backup Software

## Configure CNS and NS for NDMP

This appendix illustrates the VNX fibre HBA configuration option as well as Network Server (NS) fibre HBA configuration option for NDMP. [Figure 12 on page 163](#) shows the supported CNS fibre HBA configuration option with 510/514 Data Movers. [Figure 13 on page 164](#) shows the supported NS fibre HBA configuration option.

**Figure 12. CNS FC-SW HBA configuration with 510/514 Data Movers**

In [Figure 13 on page 164](#), the two fibre HBAs are used for tape drive connectivity.

Note:

- ◆ The LP8000 HBA is a dual channel Performance module. It is used for both storage and tape drive connectivity.
- ◆ The LP9000 HBA is available in both dual and single channel Performance module, but only the single channel module is used for tape drive connectivity.
- ◆ The single channel Performance module, LP9002L-F2, is used to connect TLUs and tape drives.
- ◆ The dual channel Performance module, LP9002DC, is used to connect storage.

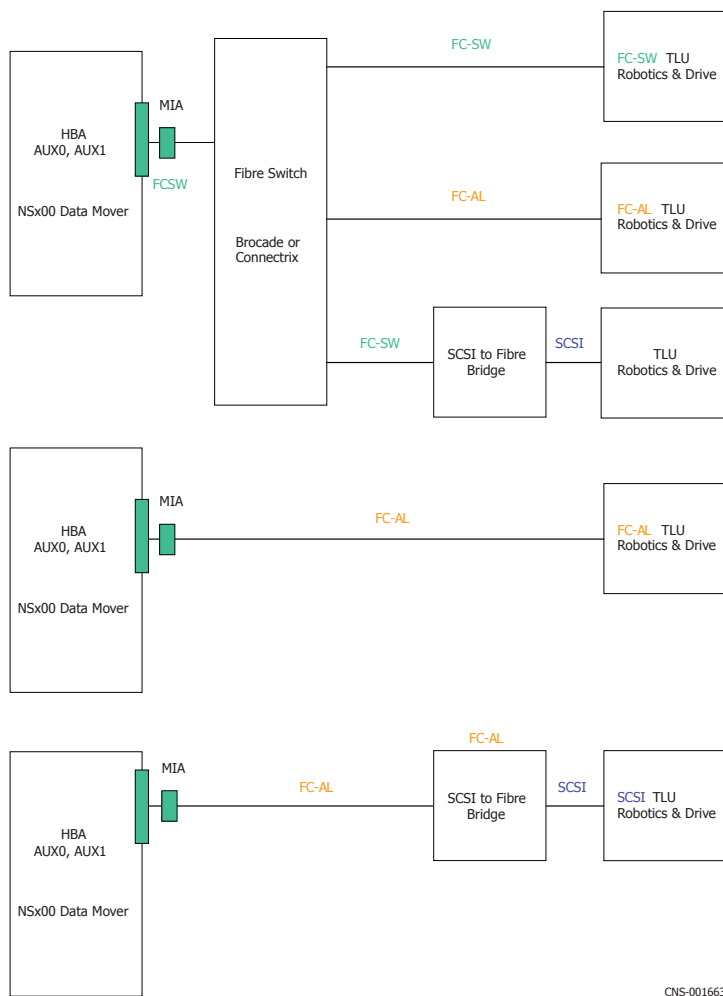

Figure 13. NS Performance-SW and FC-AL HBA configurations

## A

### **ASCII (American Standard Code for Information Interchange)**

7-bit (one byte) character-encoding scheme for representing text and controlling printers and computer communication based on the ordering of the English alphabet. US-ASCII was the most commonly used character encoding on the Internet until it was recently surpassed by UTF-8. ASCII was incorporated into the Unicode character set as the first 128 symbols, so the ASCII characters have the same numeric codes in both sets.

### **automated backup and restore**

Procedure in which a remote backup server running NDMP-compliant backup software backs up data to a tape library unit (TLU).

See also *local backup* and *remote backup*.

## B

### **backup and restore**

Technique for ensuring file system integrity and security by backing up to tape or disk a file system or incremental changes to a file system. This data can be restored later.

## C

### **character set**

Set of characters used by a language (ANSI/ASCII or Unicode). The character set affects file format (how the software stores and transmits data) and string processing (the logic with which text is manipulated).

### **checkpoint**

Point-in-time, logical image of a PFS. A checkpoint is a file system and is also referred to as a checkpoint file system or an EMC SnapSure™ file system.

See also *Production File System*.

***cumulative incremental backup***

Backup that copies all data modified since the last full backup. To restore data when cumulative incremental backups are in use, you need only the latest full and cumulative incremental backups.

See also *differential backup*, *differential incremental backup*, *full backup*, and *incremental backup*.

**D*****differential backup***

Backup that copies all data modified since the last full backup. To restore data when differential backups are in use, you need only the latest full backup and the latest differential backups.

See also *cumulative incremental backup*, *differential incremental backup*, *full backup*, and *incremental backup*.

***differential incremental backup***

Backup that copies data objects modified since the last full backup or incremental backup. To restore data when differential incremental backups are in use, the newest full backup and all subsequent differential backups are required.

See also *cumulative incremental backup*, *full backup*, and *incremental backup*.

***direct access restore (DAR)***

Data recovery operation that allows the NDMP client to directly access backed-up data anywhere in a tape set without having to traverse the tape set sequentially.

***dump***

Backup format in PAX that traverses a file tree in mixed width-first and depth-first order.

***dynamic drive sharing (DDS)***

Feature of NDMP-compliant backup software that allows NDMP servers to share tape drives.

**F*****filtering for NDMP***

Backup feature that allows administrators to specify using environmental variables in the qualified backup vendor's software, which directories and files within a file system to exclude from the backup.

***full backup***

Backup that copies a defined set of data, regardless of whether it has changed since the last backup. A full backup is the basis from which incremental backups are taken.

See also *cumulative incremental backup*, *differential incremental backup*, and *incremental backup*.

**H*****heterogeneous three-way backup***

Three-way NDMP backup involving a Data Mover, which serves as the interface to the file system or primary storage system, and a qualified third-party NDMP server, which serves as the interface to the tape devices or other secondary storage.

See also three-way backup.

## I

### **I18N**

An abbreviation for internationalization (I + 18 letters + N).

See internationalization.

### **incremental backup**

Term that encompasses both cumulative incremental backups and differential incremental backups. Any backup that copies only data objects modified since the time of some previous backup.

See also *cumulative incremental backup*, *differential incremental backup*, and *full backup*.

### **internationalization (I18N)**

The process of generalizing software such that it can be made to handle various languages and locales.

## L

### **L10N**

An abbreviation for localization (L+10 letters+N).

See localization.

### **local backup**

Procedure that backs up a file system, or incremental changes to a file system from a Data Mover to a locally attached TLU.

See also *automated backup and restore*.

### **localization (L10N)**

The process of adapting software for a specific culture or language by adding locale-specific components and translating text.

## N

### **NDMP Backup-to-Disk (NDMP2D)**

Software-based virtual tape library configured on a Data Mover that emulates a real TLU, and allows NDMP backup-to-disk functionality. This feature is sometimes referred to as a virtual tape library unit (VTLU). However, it does not provide true VTLU functionality as found in EMC Disk Library and similar storage products.

### **NDMP client**

Application that controls the NDMP session. The NDMP client runs an NDMP-compliant backup application, such as EMC NetWorker®.

### **NDMP host**

Host system (Data Mover) that executes the NDMP server application. Data is backed up from the NDMP host to either a local tape drive or to a backup device on a remote NDMP host.

**NDMP server**

NDMP process that runs on an NDMP host, which is a Data Mover in VNX for file environment.

**NDMP Volume Backup (NVB)**

EMC-specific type of NDMP backup mechanism that backs up data blocks at a volume level, rather than at a file level. NVB reads a set of disk data blocks in an efficient manner compared to the method used for traditional, file-based backups. NVB works only with EMC-qualified vendor backup software. NVB is commonly known as Volume Based Backup (VBB).

**Network Data Management Protocol (NDMP)**

Open standard network protocol designed for enterprise-wide backup and recovery of heterogeneous network-attached storage.

**P****Portable Archive Interchange (PAX)**

VNX for file archive protocol that works with standard UNIX tape formats and provides file-level backup and recovery operations.

**R****remote backup**

Remotely initiated procedure that backs up data to a TLU which can be attached to a target server different from the source Data Mover. The configuration determines whether data traverses the network.

See also *automated backup and restore* and *three-way backup*.

**T****tape library unit (TLU)**

Physical device that contains and manages sets of tape drives and cartridges.

**tar**

Backup format in PAX that traverses a file tree in depth-first order.

**three-way backup**

NDMP backup that directs data from one Data Mover through a network connection to a remote Data Mover to its attached tape library backup device.

See also *heterogeneous three-way backup* and *remote backup*.

**U****Unicode**

Family of universal character encoding standards used for representation of text for computer processing.

**UTF-8 (8-bit Unicode Transformation Format)**

Multibyte encoding form that uses an algorithmic mapping scheme to convert every Unicode value to a unique 1- to 4-byte sequence with no embedded null characters.

See *Unicode* or *UCS Transformation Format-8*.
