Dell EMC Solutions Enabler TimeFinder® Family (Mirror, Clone, Snap, VP Snap) CLI User Guide

8.2 and higher

Notes, cautions, and warnings

(i) NOTE: A NOTE indicates important information that helps you make better use of your product.

CAUTION: A CAUTION indicates either potential damage to hardware or loss of data and tells you how to avoid the problem.

WARNING: A WARNING indicates a potential for property damage, personal injury, or death.

| Tables | 1 [,] |
|---|----------------|
| Preface | |
| Chapter 1: Introduction to the TimeFinder Family | |
| Introduction to TimeFinder Family | |
| Copy Session Limits | 16 |
| TimeFinder CLI overview | 1 |
| TimeFinder Family command summary (Mirror, Clone, Snap, VP Snap) | 1 [.] |
| Chapter 2: TimeFinder/Clone Operations | 2(|
| TimeFinder/Clone overview | |
| Create TimeFinder clone copy session | |
| Create TimeFinder clone copy session in nocopy mode | |
| Create TimeFinder clone copy session in precopy mode | |
| List TimeFinder clone copy session copy mode | |
| Copy only changed data to a full copy TimeFinder clone | |
| Larger target device for TimeFinder clones | |
| Create TimeFinder clone session using the establish command | |
| Create concurrent target device for each source device in a group | |
| Perform operations on devices in TimeFinder clone device list | |
| Activate a TimeFinder clone copy session | |
| Make TimeFinder clone target device not ready to target host | |
| TimeFinder clone copy session consistency | |
| Activate TimeFinder clone copy session consistency | |
| Activate TimeFinder clone copy session for additional pair in a group | |
| Modify TimeFinder clone copy session | |
| Recreate TimeFinder clone copy device | |
| Recreate TimeFinder clone copy session in precopy mode | |
| Recreate TimeFinder clone copy session using the establish command | |
| Recreate TimeFinder clone copy session for each pair in a group | |
| Restore data from target device | |
| Split a clone device pair | |
| Terminate TimeFinder clone copy session | |
| Query TimeFinder clone copy session pairs | |
| Query TimeFinder clone copy session pairs using the -summary option | |
| Verify TimeFinder clone copy session pair states Return codes for TimeFinder clone copy verify session query | |
| TimeFinder cascaded clone copy session | |
| TimeFinder clone Restore to Target (incremental restore to cascaded clone target) | |
| TimeFinder clone Restore to Target (incremental restore to cascaded clone target) | |
| TimeFinder clone relision release to rarget (restore shap to clone target) | |
| Cascaded clone with VP Snap | |
| Using a BCV as the clone source | |
| | |

| Pair states ruling clone operations | |
|--|----|
| Example: Creating a clone from a source device | |
| Creating multiple clone copies from a standard device | |
| Cloning a copy on a remote array | |
| Cloning a local R1 standard device | |
| Cloning a copy of a local BCV device on a remote array | |
| Cloning a copy on a hop-2 array | 41 |
| Cloning copies of the same data locally and remotely | |
| Cloning multiple copies locally and remotely | |
| Cloning a copy at the tertiary site of a cascaded SRDF configuration | |
| Using composite groups to manage clone pairs across arrays | |
| Command options with device groups | 50 |
| Command options with composite groups | 53 |
| Command options with device files | 55 |
| | |

| Chapter 3: TimeFinder/Snap Operations | 57 |
|--|----|
| TimeFinder/Snap overview | |
| Creating a virtual copy session | |
| Multivirtual snaps | |
| Specifying a SAVE device pool | 59 |
| Monitoring SAVE device usage | 59 |
| Pairing an additional target device with each source device in a group | 59 |
| Copying a virtual device to another virtual device (duplicate snap) | 60 |
| Activating a virtual copy session | 60 |
| Using the establish command | 60 |
| Making the target device not ready to the host | 61 |
| Activating copy sessions consistently | |
| Activating an additional copy session for each device pair in a group | |
| Activating a duplicate snap session | |
| Recreating a virtual copy session (Enginuity 5876) | |
| Restoring data from virtual devices | 63 |
| Incrementally restoring to a source | 64 |
| Incrementally restoring to a BCV | 64 |
| Fully restoring to anywhere | |
| Terminating a virtual copy session | 66 |
| Terminating a duplicate snap session | |
| Querying snap pairs | 67 |
| Using the -summary option | 67 |
| Verifying snap pair states | |
| Using a BCV as the snap source | |
| Pair states ruling snap operations | 69 |
| Example: Creating a virtual copy from a BCV | |
| Creating multiple virtual copies | 72 |
| Creating multiple virtual copies from a standard device | 72 |
| Creating multiple virtual copies from a BCV device | 74 |
| Attaching source and target virtual devices | 76 |
| Using composite groups to manage snap pairs across arrays | 77 |
| Snapping a copy on a remote array | 79 |
| Snapping a copy from a remote BCV | 80 |
| Snapping copies of a source device's data locally and remotely | |

| Snapping multiple copies | |
|---|-----|
| Snapping a copy at the tertiary site of a cascaded SRDF configuration | |
| Snapping a copy from a clone target device | |
| Command options with device groups or composite groups | |
| Command options with device files | |
| Chapter 4: TimeFinder VP Snap Operations | |
| TimeFinder VP Snap overview | |
| Creating a VP Snap copy session | |
| Activating a VP Snap session | |
| Using the establish command | |
| Restoring a VP Snap session | |
| Terminating a VP Snap copy session | |
| Chapter 5: TimeFinder/Mirror Operations | |
| Clone Emulation mode and TimeFinder/Mirror | |
| TimeFinder/Mirror | |
| SRDF-connected sites | |
| TimeFinder/Clone Emulation | |
| TimeFinder operations overview | |
| Device external locks | |
| Disallow synchronization actions | |
| Wait for synchronization actions to complete | |
| Listing BCV devices | |
| Associating BCV devices with a device group | |
| Moving device groups Host-visible BCV devices | |
| SRDF-connected BCV device | |
| SRDF-connected BCV device | |
| Compounded remote configuration | |
| Disassociating BCV devices from a device group | |
| SRDF-connected BCV pair | |
| Remote SRDF-connected BCV pair | |
| Remote BCV or a remote BCV pair | |
| Remote BCV on the second hop of a cascaded SRDF configuration | |
| Moving BCV devices from one device group to another device group | |
| Moving a specific device | |
| Moving all BCV devices | |
| Moving remote BCV devices | |
| Managing BCV devices with composite groups | |
| Associating BCV devices with a composite group | |
| Disassociating BCV devices from a composite group | |
| Moving BCV devices to a composite group | |
| Establishing BCV pairs | |
| Specifying the default method for establishing BCV pairs | |
| Incrementally establishing BCV pairs | |
| Automatically converting an incremental establish to a full establish | |
| Incrementally establishing multiple BCV pairs | 117 |
| Splitting BCV pairs | |

| SRDF-connected BCV pairs | 120 |
|---|-----|
| Second-level remote BCV pairs | |
| Hop 2 BCV pairs in a cascaded SRDF configuration | 121 |
| Remote copy with BCV split | |
| Performing a reverse split | |
| Splitting concurrent BCV pairs | |
| TimeFinder consistent split | |
| Consistent split using Enginuity Consistency Assist | |
| Fully restoring BCV pairs | 128 |
| Specifying the default method for restoring BCV pairs | |
| Instantly restoring multiple BCV pairs | 130 |
| Incrementally restoring BCV pairs | 131 |
| Multiple BCV pairs | 133 |
| SRDF-connected BCV pairs | 133 |
| Second-level remote BCV pairs | |
| Hop 2 BCV pairs in a cascaded SRDF configuration | 134 |
| Protecting BCV data during full or incremental restores | |
| Cancelling BCV pairs | 135 |
| Querying BCV pairs | |
| Using the -summary option | 137 |
| Verifying BCV pair states | 137 |
| Using composite groups to manage BCV pairs across arrays | |
| Preferred attachment of BCVs (optional operations) | |
| Detaching BCV preferences from devices | |
| Attaching remote devices as preferred pairs | |
| Detaching BCV preferences for remote devices | |
| Attaching second-level remote devices as preferred pairs | |
| Detaching BCV preferences from second-level remote devices | |
| Attaching hop 2 devices as preferred pairs in a cascaded SRDF configuration | |
| Detaching BCV preferences from hop 2 devices in a cascaded SRDF configuration | |
| Script summary for typical TimeFinder operations | |
| Script example for multi-BCV environment | |
| BCV pair states | |
| Transient BCV pair states | |
| BCV actions and applicable states | |
| Command options with device groups | |
| Command options with composite groups | |
| Command options with device files | |
| Various remote multihop configurations | |
| System-wide device groups | |
| Commands to various multihop devices and links | |
| Second-level controls for multihop SRDF environments | |
| Using the -remote option on multihop split actions | |

As part of an effort to improve its product lines, EMC periodically releases revisions of its software and hardware. Therefore, some functions described in this document might not be supported by all versions of the software or hardware currently in use. The product release notes provide the most up-to-date information on product features.

Contact your EMC representative if a product does not function properly or does not function as described in this document.

NOTE: This document was accurate at publication time. New versions of this document might be released on EMC Online Support (https://support.emc.com). Check to ensure that you are using the latest version of this document.

Purpose

This document is part of the EMC Solutions Enabler documentation set, and describes how to use TimeFinder Mirror, Clone, Snap, and VP Snap.

Audience

This document is intended for use by advanced command-line users and script programmers to manage various types of control operations on arrays and devices using the SYMCLI commands of the EMC Solutions Enabler software.

Related documentation

The following documents provide additional Solutions Enabler information:

| EMC Solutions Enabler, VSS Provider, and SMI-S Provider Release Notes | Describes new features and any known limitations. |

Special notice conventions used in this document

EMC uses the following conventions for special notices:

(i) NOTE: Indicates a hazardous situation which, if not avoided, will result in death or serious injury.

WARNING: Indicates a hazardous situation which, if not avoided, could result in death or serious injury.

CAUTION: Indicates a hazardous situation which, if not avoided, could result in minor or moderate injury.

(i) NOTE: Addresses practices not related to personal injury.

(i) NOTE: Presents information that is important, but not hazard-related.

Typographical conventions

EMC uses the following style conventions in this document:

Table 1. Typographical conventions used in this content

| Bold | Used for names of interface elements, such as names of windows, dialog boxes, buttons, fields, tab names, key names, and menu paths (what the user specifically selects or clicks) |
|------------------|--|
| Italic | Used for full titles of publications referenced in text |
| Monospace | Used for: System code System output, such as an error message or script Pathnames, filenames, prompts, and syntax Commands and options |
| Monospace italic | Used for variables |
| Monospace bold | Used for user input |
| [] | Square brackets enclose optional values |
| | Vertical bar indicates alternate selections - the bar means "or" |
| { } | Braces enclose content that the user must specify, such as x or y or z |
| | Ellipses indicate nonessential information omitted from the example |

Where to get help

EMC support, product, and licensing information can be obtained as follows:

() NOTE: To open a service request through EMC Online Support, you must have a valid support agreement. Contact your EMC sales representative for details about obtaining a valid support agreement or to answer any questions about your account.

| Product information | For documentation, release notes, software updates, or information about EMC products, go to EMC Online Support at https://support.emc.com . |
|------------------------|--|
| Technical support | EMC offers a variety of support options. |

Support by Product — EMC offers consolidated, product-specific information on the Web at: https://support.EMC.com/products

The Support by Product web pages offer quick links to Documentation, White Papers, Advisories (such as frequently used Knowledgebase articles), and Downloads, as well as more dynamic content, such as presentations, discussion, relevant Customer Support Forum entries, and a link to EMC Live Chat.

• EMC Live Chat — Open a Chat or instant message session with an EMC Support Engineer.

To activate your entitlements and obtain your VMAX license files, visit the Service Center on https:// support.EMC.com, as directed on your License Authorization Code (LAC) letter emailed to you.

- For help with missing or incorrect entitlements after activation (that is, expected functionality remains unavailable because it is not licensed), contact your EMC Account Representative or Authorized Reseller.
- For help with any errors applying license files through Solutions Enabler, contact the EMC Customer Support Center.
- If you are missing a LAC letter, or require further instructions on activating your licenses through the Online Support site, contact EMC's worldwide Licensing team at licensing@emc.com or call:
 - North America, Latin America, APJK, Australia, New Zealand: SVC4EMC (800-782-4362) and follow the voice prompts.
 - EMEA: +353 (0) 21 4879862 and follow the voice prompts.

Introduction to the TimeFinder Family

This chapter introduces the EMC Solutions Enabler TimeFinder Family (Mirror, Clone, Snap VP Snap) and the SYMCLI commands for each of these products.

Topics:

Introduction to TimeFinder Family

Introduction to TimeFinder Family

EMC TimeFinder family of replication products (Mirror, Clone, Snap, VP Snap) allows nondisruptive creation and management of point-in-time copies of data, enabling simultaneous action of business tasks that were previously sequential. TimeFinder creates and manages point-in-time copies of critical data that can be used for backups, decision support, and to refresh data warehouse, test, and development environments.

The ability to access source data during the TimeFinder copy operation eliminates the backup window and provides benefits such as accelerated upgrades and high availability. TimeFinder can also shorten the maintenance window, minimize infrastructure costs, and improve service levels.

TimeFinder Mirror, Clone, Snap, and VP Snap are supported on VMAX arrays running Enginuity 5773 and 5876. Each TimeFinder product has it's own features and use cases. These TimeFinder products require a target volume to retain snap or clone data. The following chapters provide more information about operations using these TimeFinder products:

- TimeFinder/Clone Operations on page 20
- TimeFinder/Mirror Operations on page 94
- TimeFinder/Snap Operations on page 57
- TimeFinder VP Snap Operations on page 91
- () NOTE: Legacy TimeFinder operations can be run on arrays running HYPERMAX OS 5977 and higher using "as is" commands and scripts. SnapVX transparently interprets legacy commands and automatically maps TimeFinder/Clone, TimeFinder VP Snap, and TimeFinder/Mirror commands to the executable of the appropriate SnapVX command. The following restrictions apply when running legacy operations:
 - Legacy commands (commands used for TimeFinder Clone, Mirror, Snap, and VP Snap) provide TimeFinder functions and features only for Enginuity 5876. SnapVX scalability and storage group operations are not supported.
 - Legacy TimeFinder sessions and SnapVX snapshots cannot coexist on the same device. EMC VMAX3 Family Product Guide for VMAX 100K, VMAX 200K, VMAX 400K with HYPERMAX OS provides more information.

NOTE: Any state table changes or any issues with legacy TimeFinder operations running on arrays with HYPERMAX OS 5977 are documented in the latest version of the Solutions Enabler Release Notes.

Copy Session Limits

VMAX arrays running Enginuity 5773 and 5876 support up to 16 sessions per source device, which can be used for TimeFinder/ Clone, TimeFinder/Snap, SRDF/Star, Solutions Enabler Open Replicator (ORS), or Symmetrix Differential Data Facility (SDDF) operations. TimeFinder VP Snap allows an additional 32 sessions per device. This limits the number of available copies that can be created.

() NOTE: Not all VMAX arrays support all of these technologies. In addition, the number of supported copy sessions per source device may vary on certain platforms. Refer to the product guide for specific VMAX arrays for details on supported TimeFinder features.

Table 2. Number of session slots used per operation

| Operation | Session slots |
|---------------------------------|---|
| TimeFinder/Snap | One session slot per snap session, plus an additional session slot for restore operations. For arrays running Enginuity 5876: One session slot per snap session, plus two additional session slots for restore operations. |
| Multivirtual snap | One session slot (regardless of the number of sessions), plus an additional session slot reserved for restore operations. For arrays running Enginuity 5876: One session slot per session, plus two additional session slots for restore operations. |
| TimeFinder/Clone | Two session slots per copy session, unless using the - nodifferential option, in which case one session slot is used per copy session. |
| TimeFinder/Clone Emulation mode | Two session slots. |
| ORS | One session slot per ORS session, and one session slot for each additional session unless the session was created with the -nodifferential option. |
| SRDF/Star | Two session slots. |
| SRDF/A | One session slot. |
| SDDF | One session slot per SDDF session |

TimeFinder CLI overview

This section provides an overview of the TimeFinder Family Command Line Interface (CLI).

 ${\sf TimeFinder\ commands\ include:\ symclone,\ symsnap,\ symbol,\ and\ symmir.}$

• The TimeFinder/Clone symclone command creates a point-in-time copy.

The TimeFinder/Clone operations are create, activate, recreate and activate (or establish that combines the two procedures into one operation), restore, and terminate. TimeFinder/Clone Operations on page 20 describes the symclone command and the TimeFinder/Clone operations in greater detail.

• The TimeFinder/Snap symsnap command creates virtual device copy sessions between a source device and multiple virtual (VDEV) target devices. These virtual devices only store pointers to changed data blocks from the source device, rather than a full copy of the data.

The TimeFinder/Snap operations are create, activate, recreate, restore and terminate. TimeFinder/Snap Operations on page 57 describes the symsnap command and the TimeFinder/Snap operations in greater detail.

• TimeFinder VP Snap utilizes the symclone command to create space-efficient snaps for thin devices. VP Snap provides the efficiency of Snap technology with improved cache utilization and simplified pool management. TimeFinder VP Snap Operations on page 91 describes how to use the symclone command to perform VP Snap operations.

TimeFinder Family command summary (Mirror, Clone, Snap, VP Snap)

(i) NOTE: The EMC Solutions Enabler CLI Command Reference provides complete details about command syntax.

Table 3. TimeFinder command summary

| Command | Description |
|---------|--|
| 1 | Performs TimeFinder/Clone control operations on standard or BCV devices: Creates a copy session for making multiple data copies between a source device and target devices. |

Table 3. TimeFinder command summary (continued)

| Command | Description |
|---------|---|
| | Creates and activates a copy session Modifies the mode in which a copy session is operating. Activates a copy session to make data instantly accessible to multiple target hosts. Copies (incrementally) all subsequent changes made to a source device to a target device, after a clone session is fully copied. Restores data from a target device back to a source device or to another device. Terminates a copy session to remove holds on target devices and delete device pair information from the array. Queries information about the state of mirroring for multiple copy sessions. Verifies the state for selected devices. Lists all copy sessions that have been created on the array. Performs TimeFinder VP Snap control operations: Creates space-efficient snaps for thin devices Incrementally restores data back to the original source |
| symsnap | device without requiring that the source device is fully copied Performs Snap control operations for virtual copy sessions from normal devices to virtual devices. The source device can be either a standard or a BCV device and the target device must be a virtual device (VDEV). Creates a virtual copy session for making multiple data |
| | copies between a source device and up to 15 target devices Enginuity version 5876 supports up to 14 target devices. Multivirtual snap supports up to 128 target devices. Specifies a particular SAVE pool for use in a virtual copy session. Activates a virtual copy session to make data instantly accessible to multiple target hosts. |
| | Recreates a snap session on existing VDEVs to prepare to active a new point-in-time image and is only valid when issued against previously activated sessions. Terminates a virtual copy session to remove holds on target devices and delete device pairing information from the array. Queries information about the state of mirroring for multiple copy sessions. |
| | Verifies device states. Attaches and detaches target devices as the preferred devices to use in a requested Snap operation. Restores a virtual device to another device, or to the original device. Duplicates a point-in-time copy of a virtual device, which is paired in a previously activated snap session, to another virtual device. Lists all virtual copy sessions that have been created on the array. |
| symbov | Performs operations on one or more BCV devices:Associates a device pair. |

Table 3. TimeFinder command summary (continued)

| Command | Description |
|---------|---|
| | Disassociates a device pair. Lists all BCV devices in the array. Moves a BCV device from one group to another. Removes all BCV devices from the specified device group. |
| symmir | Performs control operations on BCV device pairs including: Establishes (mirror) one or all standard devices with one or more BCV devices. The operation can be a full or incremental establish. Restores one or all standard devices from one or more BCV devices that are associated locally or remotely. The operation can be a full or incremental restore. Splits one or all BCV devices from one or more standard devices. Returns information about the state of mirroring of one or all BCV device pairs. Cancels the existing internal SDDF session between the specified standard and BCV devices. Lists all BCV sessions created on an array. |

 $_{\mbox{\scriptsize a.}}$ Supported in VMAX3 arrays with HYPERMAX OS in emulation mode.

TimeFinder/Clone Operations

This chapter describes how to perform TimeFinder/Clone operations using the SYMCLI **symclone** command.

Topics:

- TimeFinder/Clone overview
- Create TimeFinder clone copy session
- Activate a TimeFinder clone copy session
- Modify TimeFinder clone copy session
- Recreate TimeFinder clone copy device
- Restore data from target device
- Split a clone device pair
- Terminate TimeFinder clone copy session
- Query TimeFinder clone copy session pairs
- Verify TimeFinder clone copy session pair states
- TimeFinder cascaded clone copy session
- Using a BCV as the clone source
- Creating multiple clone copies from a standard device
- Cloning a copy on a remote array
- Cloning copies of the same data locally and remotely
- Cloning multiple copies locally and remotely
- Cloning a copy at the tertiary site of a cascaded SRDF configuration
- Using composite groups to manage clone pairs across arrays
- Command options with device groups
- Command options with composite groups
- Command options with device files

TimeFinder/Clone overview

For a high-level overview of TimeFinder/Clone functionality, refer to the EMC Symmetrix TimeFinder Product Guide.

TimeFinder/Clone operations are performed using the symclone command to create clone copies of a source device on one or multiple target devices.

A single source device can have up to 16 clone copy sessions. Eight full data copies can created simultaneously, without disruption to database production activity, and eight more can be created once the first eight copies are complete. Copy Session Limits on page 16 provides additional details about the allowable number of copies that can be created.

(i) NOTE: Data Domain devices are not supported as TimeFinder/Clone source or target devices.

Create TimeFinder clone copy session

Description

The symclone create commands defines the clone copy session requirements and sets the track protection bitmap on the source device to detect which tracks are being accessed by the target host or written to by the source host.

For clone copying, the default setting for background copying is -copy option. Data begins copying in the background when the clone session is activated and a full copy will become available to the host. While background copying, the state of the device pair is *CopyInProgress*. When the operation completes, the state goes to *Copied*. The copy session must be activated before the target host can access the data. However, once the session is activated, the data is available immediately to the target host.

NOTE: The -differential option is specified by default. Use the -nodifferential flag to create a nondifferential session, which cannot be recreated.

Examples

To create a clone copy session between source device DEV001 and target device DEV005 in group ProdDB, enter:

symclone -g ProdDB create DEV001 sym 1d DEV005

Rules and restrictions

The following rules and restrictions apply to a clone copy:

- The target device is made Not Ready to its host and placed on hold status for clone copy session activity. This prevents
 other control operations from using the device.
- The device pair state transitions from CreateInProgress to Created when complete.
- The clone copy does not become accessible to its host until the copy session is activated. Activate a TimeFinder clone copy session on page 24 contains greater detail.
- A device pair cannot be verified that it is in the CreatelnProgress state. After the copy session completes, issue a
 symclone verify -created command to verify that the clone pair is successfully created.
- If a copy session is created and not activated, it can be terminated. However, the data on the target device should be considered invalid.

Create TimeFinder clone copy session in nocopy mode

Description

When activating a copy session in nocopy mode, the default device pair state is CopyOnAccess. After activating the copy session, only those tracks that have been written to the source or written/read from the target are copied to the target device. A full data copy to the target device does not occur unless all of the device tracks are accessed or written to while participating in the active session.

If a write occurs to the source device, old data is copied to the target device. If a write occurs to the target device, new data is written to the target device. When Enginuity detects that a source-protected track was written, it copies the track to the target device and unprotects the track before accepting the new write. Data from the source then becomes available to a target-connected host during the active session.

The CopyOnAccess device pair state can be modified to CopyOnWrite by setting the following parameter in the Options file, or environment variable to ENABLE. The environment variable will override the default settings specified in the options file.

```
SYMAPI CLONE COPY ON WRITE = ENABLE | DISABLE
```

Once the CopyOnWrite is enabled as the default pair state and the copy session is activated, all reads are handled from the source device, and writes to the source device or target device during the active copy session result in the data being copied to a target device.

Examples

To create a clone copy session in -nocopy mode, and define the clone target device DEV005 from the source device DEV001 in group ProdDB, enter:

symclone -g ProdDB create DEV001 sym ld DEV005 -nocopy

Create TimeFinder clone copy session in precopy mode

Description

The *Precopy* mode starts copying tracks in the background, before activating a copy session, and allows the early movement of data before the point-in-time clone copy is established. The precopy process checks for any new writes to copy to the target device until the copy session is activated. Once activated, the normal background copy mechanism starts and the precopy operation ends. When using the *Precopy* mode, the target device is not ready to the host until the session is activated.

Examples

To create a clone copy session using the -precopy option, enter:

```
symclone -g ProdDB create -precopy DEV001 sym ld DEV005
```

List TimeFinder clone copy session copy mode

Description

To see a list of sessions that are using a particular copy mode, specify the copy option with the symclone list command.

Options

-copy Lists acitvated sessions with background copy active. -nocopy Lists activated sessions with no background copy. -precopy Lists session with precopying active. Precopy mode starts copying tracks in the background before the session is activated.

Examples

To see a list of sessions with the background copy active, enter:

symclone list -copy

Copy only changed data to a full copy TimeFinder clone

Description

Differential copying (subsequent cloning to the same target) copies only those device tracks that have changed since the full clone was performed (that is, only new writes to the source device will be copied). A differential clone operation requires that the copy session that existed for the full clone still exists. Because a full clone is required, the -differential option must be specified with the -copy or -precopy option. The -nocopy option is not allowed.

Examples

To copy only changed data to a full copy clone, enter:

```
symclone -g ProdDB create -copy -differential DEV001 sym ld DEV005
```

The -differential option creates a SDDF (Symmetrix Differential Data Facility) session for the source.

Larger target device for TimeFinder clones

A target device can be larger than the source device, and requires the following SYMCLI environment variable be set:

SYMCLI_CLONE_LARGER_TGT = ENABLED

The following limitations apply:

- Restore is not allowed.
- Full copy support only; must use -nodifferential.
- VP Snap is not supported.
- Concatenated metadevices are not supported.
- When using this feature on striped metadevices, the source and target devices must contain the same number of
 metamembers. However, the target device members can be larger than the source device members.
- Exact pairing are the only operations allowed, as follows:
 - -file
 - -g or -cg with -exact
 - -g or --cg with source and target ldev name supplied

Create TimeFinder clone session using the establish command

Description

Use the symclone establish command, to create and then immediately activate a copy session with a single command.

Examples

To create and then activate a copy session, enter:

symclone -g ProdDB establish DEV001 sym 1d DEV005 -full

NOTE: The symclone establish command sets the target device to *Not Ready* for a short period time. If using a filesystem, unmount the target host before performing the establish command.

Create concurrent target device for each source device in a group

Description

When working with a composite or device group, use the symclone create or symclone establish command with the option -concurrent option to pair an additional target device with each source device in the group. When the copy session is created, an additional target device is paired with each source device in the group. For example, if there are two target devices paired with each source device in the group before creating the session, after the session is created there will be three target devices paired with each source device.

Examples

To pair an additional target device with each source device in group ProdDB, enter:

```
symclone -g ProdDB create -concurrent
```

To verify that each source device in group ProdDB has multiple targets, enter:

symclone -g ProdDB verify -created -concurrent

Perform operations on devices in TimeFinder clone device list

Description

When working with a composite or device group, use the -tgt option to use devices from a local target list as targets for the specified action. See options below that can be paired with the with the -tgt option. See EMC Solutions Enabler Array Management CLI Product Guide for more information on creating and managing clone target lists.

The -tgt option works with all symclone actions, except for query and verify, as these actions are source device oriented and list all target devices paired with source devices by default, including TGT and RTGT.

When working with specific pairs, the symclone command supports the following target devices:

```
sym ld LdevName
sym dev SymDevName
sym pd PdevName
```

Syntax

For device groups, to copy from a local standard device to a local target, use the following syntax:

```
symclone -g DgName action [-tgt [-bcv] | -rdf [-bcv | -tgt] | -rbcv -tgt | -rrbcv |
-hop2 [-tgt]]
```

For composite groups, to copy from a local standard device to a local target, use the following syntax::

```
symclone -cg CgName action [-tgt [-bcv] | -rdf [-bcv | -tgt] | -rbcv -tgt | -rrbcv |
-hop2 [-tgt]]
```

Options

-rdf

Specifies remote attached devices (RTGTs) as the target devices.

-hop2

Specifies devices remotely associated on the second hop of a cascaded SRDF configuration (2TGTs) as the target devices.

Activate a TimeFinder clone copy session

Description

Activating the copy session starts the copy from the source device to the target device, and places the target device in the Read/Write state. The target host can access the cloned data and has access to data on the source host until the copy session is terminated.

NOTE: Cloned data is made available as a point-in-time copy at the time of activation and not at the time that the session was created.

To activate the clone copy session between target device DEV005 and source device DEV001, enter:

symclone -g ProdDB activate DEV001 sym 1d DEV005

Make TimeFinder clone target device not ready to target host

Examples

To active the clone copy session between target device DEV005 and source device DEV001 and make the target device Not Ready to it's host, enter:

symclone -g ProdDB activate DEV001 sym ld DEV005 -not_ready

The clone copy can be made read/write enabled to the host using either the symdg ready or symdev ready command.

TimeFinder clone copy session consistency

The symclone activate command is used with the -consistent option to create clone copies that are consistent with the database up to the point where activation occurs. This feature is implemented using either the Enginuity Consistency Assist (ECS) feature or SRDF/A.

NOTE: If the R2 is in a consistent state and the copy session is pre-copying data, setting the consistent option invokes SRDF/A to maintain consistency, instead of ECA.

This feature is used to create clone copies that are consistent with the database up to the point in time that the activation occurs. The feature suspends writes to the source devices during the activation. When the activation has completed, writes are resumed and the target device contains a consistent production database copy of the source device at the time of activation.

The ECA feature is used to consistently activate copy sessions across multiple, heterogeneous hosts. ECA requires either a control host with no database, or a database host with a dedicated channel to the gatekeeper devices. In a SAN environment, gatekeepers and data devices may share the same FA port on the array but the gatekeepers must be available on a separate host HBA from the data devices. This requires a dedicated channel from a host HBA to the switch used to access only gatekeepers and not devices that contain host data. In this configuration, write intensive environments SYMAPI are able to freeze and then thaw I/O to the devices in the device group within the ECA window, regardless of the number of outstanding I/Os held by the HBA.

For detailed information on gatekeeper management, refer to the EMC Solutions Enabler Installation Guide.

The following figure shows how a control host can consistently activate a copy session that uses three database hosts that access devices on an array.

NOTE: When activating a copy session from an R2 device, if the SRDF pair is in adaptive copy mode, the -consistent option is not allowed.

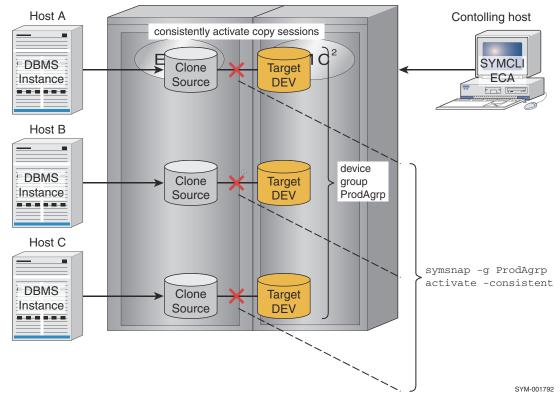

Figure 1. TimeFinder/Clone consistent activate using ECA

A device group, composite group, or a device file must be created on the controlling host for the target database to be consistently activated. Device groups can be created to include all of the devices being accessed or defined by database host access.

As shown in the above example, consistent activation of all copy sessions for Hosts A, B, and C can be done with a single command using a device group (ProdAgrp) that includes all devices accessed by the three hosts. However, for consistent activation of copy sessions for a single host (Host A), without affecting other hosts, use a device group that includes only the devices accessed by the single host.

Activate TimeFinder clone copy session consistency

Examples

To activate a consistent copy of the devices in group ProdDB, enter:

```
symclone -g ProdDB activate -consistent
```

Activate TimeFinder clone copy session for additional pair in a group

Examples

To activate a copy session for an additional clone pair in group ProdDB, enter:

(i) NOTE: The copy session must exist prior to issuing the command.

symclone -g ProdDB activate -concurrent

Modify TimeFinder clone copy session

Description

Use the set mode command to modify the clone copy session operating mode.

Options

сору

Initiates a copy once the session is activated, or starts a copy immediately if the session is already activated.

nocopy
Session becomes CopyOnWrite/CopyOnAccess once the session is activated and there is no full device copy, or the copy stops if the session is already activated.

i NOTE:
precopy
Starts copy in the background before session is activated. If the session is created without the precopy option then changing to this mode immediately puts it immediately into effect.. Once in Precopy mode the session mode cannot be changed to Nocopy mode. Once the session is activated the

session changed to Copy mode. For more information on Precopy mode refer to Create TimeFinder clone

Examples

To change a copy session from Copy mode to Nocopy mode, enter:

copy session in precopy mode on page 22.

```
symclone -g ProdDB set mode nocopy
```

Recreate TimeFinder clone copy device

Description

Use the symclone recreate command to incrementally copy all subsequent changes made to the source device (made after the point-in-time copy was activated) to the target device.

() NOTE: With Enginuity 5876.159.102 and higher, clone copy sessions can be recreated without terminating TimeFinder/Snap or VP Snap sessions that are cascading off of the clone target. TimeFinder State Rules Reference on page 160 provides additional details.

Example

To recreate the copy session between target device DEV005and source device DEV001 in group ProdDB, enter: , enter:

symclone -g ProdDB recreate DEV001 sym 1d DEV005

Restrictions

The following restrictions apply for the symclone recreate operation:

• The copy session must not have been created with the -nocopy or -nodifferential option.

- The session must have been activated to establish the new point-in-time copy.
- While in the *Recreated* state, the target device remains *Not Ready* to the host.

Recreate TimeFinder clone copy session in precopy mode

Description

The -precopy option is used with the symclone recreate command to start copying tracks in the background, before the copy session is activated. When using this option, a point-in-time copy is established when the session is activated.

While in the *Recreated* state, the precopy process never fully completes. Instead, the process keeps checking for new writes to be pre-copied to the target device until the session is activated. Once activated, the normal background copy mechanism takes over and the pre-copy operation ceases.

The -precopy option must be used with the recreate operation if the session was initially created as a Precopy session.

Examples

To recreate a clone copy session using the -precopy option, enter:

symclone -g ProdDB recreate DEV001 sym 1d DEV005 -precopy

Recreate TimeFinder clone copy session using the establish command

Description

Use the symclone establish command, to recreate and then immediately activate a copy session with a single command.

Options

-concurrent

Activates an existing clone session for an additional clone pair in a group.

Examples

To recreate and then activate a previous copy session, enter:

symclone -g ProdDB establish DEV001 sym 1d DEV005

NOTE: The symclone establish command sets the target device to *Not Ready* for a short period time. If using a filesystem, unmount the target host before performing the establish command.

To recreate and then activate a copy session for an additional clone pair in group ProdDB, enter:

symclone -g ProdDB establish -concurrent

Recreate TimeFinder clone copy session for each pair in a group

When working with either a composite or device group, use the -concurrent option with the **recreate** action to recreate a clone session for each clone pair in a group.

Examples

To recreate a copy session for each clone pair in group **ProdDB**, enter:

```
symclone -g ProdDB recreate -concurrent
```

Restore data from target device

Use the symclone restore command to copy target data to another device (*full restore*), or back to the original source device (*incremental restore*). The restore operation requires that the session is differential and the device pair is in the *Copied* state.

With a full restore (-full), the original session terminates and a copy session to the target of the restore starts.

With an incremental restore, the original session copy direction reverses and changed data is copied from the target device to the source device.

Examples

To fully restore data from the original target device (DEV005) to a device (DEV006) that was not involved in the original clone session, enter:

symclone -g ProdDB restore -full DEV006 sym 1d DEV005

() NOTE: When constructing a symclone restore command, the device receiving the data always appears first in the command, followed by the device from which the data is being copied. In the above command, DEV006 is the target of the data being copied from DEV005.

Split a clone device pair

Description

Use the symclone split command to *split* a clone device pair that is in the *Restored* state. The original source device becomes the source device for a future copy, and the establish or recreate command can be used.

Examples

To split the device pair DEV001 and DEV005, enter:

```
symclone -g ProdDB split DEV001 sym 1d DEV005
```

Terminate TimeFinder clone copy session

Description

Terminating a copy session deletes the pairing information in the array and removes any hold on the target device. Terminating a session while the device pairs are in the *CopyOnAccess, CopyOnWrite,* or *CopyInProg* state causes the session to end. If the application has not finished accessing all of the data, the target copy is not a full copy.

The symclone terminate command is allowed for all clone pair states.

Examples

To terminate the copy session for device pair DEV001 and DEV005, enter:

symclone -g ProdDB terminate DEV001 sym 1d DEV005

(i) **NOTE:** A created and activated copy session may be terminated, but the data on the target device is not valid unless the device state is *COPIED*.

If the state is *CopyInProg*, then apply the -symforce option to terminate the session. This leaves the target copy as an incomplete copy.

If the -not_ready option is applied to the copy session, Solutions Enabler leaves the target devices in their prior *Ready* or *NotReady* state at the completion of the terminate operation. If the -not_ready option is not applied to the copy session, Solutions Enabler leaves the target devices in the *Ready* state at the completion of the terminate, regardless of their state prior to the terminate operation.

Query TimeFinder clone copy session pairs

Description

The symclone query command is sent through a gatekeeper device to the array and returns information about the state of a clone pair, all clone pairs in a device group, a composite group, or a device file.

Syntax

To query target devices in a device group, composite group, or device file use the following syntax:

```
symclone -g DgName query
symclone -cg CgName query
symclone -f[ile] FileName query
```

Options

-offline

Retrieves target device information for the host database.

Examples

To query the state of the clone pairs in the prod device group, enter:

symclone -g prod query

To query the state of SRDF-connected clone pairs in the prod device group, enter any of the following:

```
symclone -g prod query -rdf
symclone -g prod query -rdf -bcv
symclone -g prod query -rrbcv
symclone -g prod query -hop2
```

The results of the query include the following information for each member of a clone pair in a device group:

- Logical device name
- Device name
- Number of invalid tracks
- Clone pair state

Query TimeFinder clone copy session pairs using the -summary option

Description

Use the -summary option with the symclone query command, to report the following results:

- Number of clone pairs in each clone pair state
- Number of invalid tracks

Options

-i, -c

Reports the sychronization rate and estimated time to complete a copy, for a specified time period (-c) and at specified time intervals (-i)

Examples

To view the number of clone pairs in the prod device group that are in each state, and to view the estimated time to completion, enter:

symclone -g prod query -summary -i 60

The -summary option can be used with the symclone verify command.

Verify TimeFinder clone copy session pair states

Description

Use the **symclone verify** command to verify that one or all clone pair(s) in a device group, composite group, or device file are in a particular state. The command can be used in scripts to verify that the clone device pair(s) are in a particular state prior to executing subsequent Solutions Enabler commands. If no device state qualifiers are specified, the default for the symclone verify, is to check for the *Copied* state.

Syntax

To verify target devices in a device group, composite group, or device file, use the following syntax:

```
symclone -g DgName verify
symclone -cg CgName verify
symclone -f[ile] FileName verify
```

Options

(i) NOTE: Add the -concurrent option with each of the following options to verify a concurrent clone pair.

-copied

| | Verifies that the copy sessions are in the <i>Copied</i> state (default). |
|---------------|--|
| -copyinprog | Verifies that the copy sessions are in the CopyInProgress state. |
| -copyonaccess | Verifies that the copy sessions are in the CopyOnAccess state. |
| -copyonwrite | Verifies that the copy sessions are in the <i>CopyOnWrite</i> state. |
| -created | Verifies that the copy sessions are in the <i>Created</i> state. |
| -precopy | Verifies that the copy sessions are in the <i>Precopy</i> state. |
| -cycled | Verifies that the copy sessions have completed one precopy cycle. This options requires the -precopy |
| -recreated | option. |
| -restored | Verifies that the copy sessions are in the <i>Recreated</i> state. |
| -split | Verifies that the copy sessions are in the <i>Restored</i> state. |
| - | Verifies that the copy sessions are in the Split state. |

Examples

() NOTE: For a multi-clone or concurrent clone device group, specifying the clone on the command line ensures that the verify operation checks the status of the clone. Otherwise, the verify operation checks the status of the standard device, which may no longer be established with the clone that you want to verify.

To return the status of standard device DEV001 with its last paired clone, enter:

```
symclone -g ProdBgrp verify DEV001
```

To return the status of a specific clone pair (DEV001 with DEV005), enter:

```
symclone -g ProdBgrp verify DEV001 sym ld DEV005
```

To return the status every 30 seconds until all clone pairs in the device group (ProdBgrp) or composite group (MyConGrp) are in the Copied state, enter:

(i) NOTE: If no device state qualifier is specified the command checks for the Copied state.

```
symclone -g ProdBgrp -i 30 verify
```

symclone -cg MyConGrp -i 30 verify

Possible return codes at 30-second intervals are zero (code symbol CLI_C_SUCCESS) if the verify criteria is met, or one of the return codes if none or not all of the devices meet the verify criteria. Refer to Return codes for TimeFinder clone copy verify session query on page 32 for return codes.

Return codes for TimeFinder clone copy verify session query

Table 4. Return codes for verifying TimeFinder clone copy session

| Options used with Verify command | Code number | Code symbol |
|----------------------------------|-------------|----------------------|
| -copied | 55 | CLI_C_NOT_ALL_COPIED |

| Options used with Verify command | Code number | Code symbol |
|----------------------------------|-------------|------------------------------|
| -copied | 56 | CLI_C_NONE_COPIED |
| -copyinprog | 53 | CLI_C_NOT_ALL_COPYINPROG |
| -copyinprog | 54 | CLI_C_NONE_COPYINPROG |
| -copyonaccess | 57 | CLI_C_NOT_ALL_COPYONACCESS |
| -copyonaccess | 58 | CLI_C_NONE_COPYONACCESS |
| -copyonwrite | 66 | CLI_C_NOT_ALL_COPYONWRITE |
| -copyonaccess | 67 | CLI_C_NONE_COPYONWRITE |
| -created | 60 | CLI_C_NOT_ALL_CREATED |
| -created | 61 | CLI_C_NONE_CREATED |
| -cycled | 75 | CLI_C_NOT_ALL_PRECOPY_CYCLED |

Table 4. Return codes for verifying TimeFinder clone copy session (continued)

TimeFinder cascaded clone copy session

In environments running Enginuity 5876, the target device of a clone session can be used as the source for one or more clone sessions. This cascading clone capability allows a clone operation to take place with a device that is already involved in a clone operation without ending the first clone session.

As the figure below shows, cascaded sessions are accepted from left to right. This means you can use TimeFinder to clone device A to device B. Then, while the relationship between A and B is preserved, you can clone device B to device C. If you have session A -> B -> C, then session B -> C can only be activated after session A -> B has been activated. Precopy sessions are allowed.

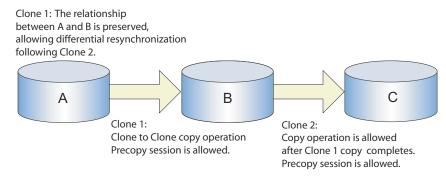

Figure 2. Clone from clone target (both sessions are cascaded clone)

Cascaded clone on thin devices is supported in environments running Enginuity 5876.

Incremental restores of clone targets to source devices with active TimeFinder/Snap or VP Snap sessions is supported with Enginuity 5876.159.102 and higher with Solutions Enabler version 7.5 and higher.

Mixed thick and thin devices are not supported. All devices in a cascaded session must be thick or thin.

TimeFinder clone Restore to Target (incremental restore to cascaded clone target)

Restore to Target (RTT) allows you to perform an incremental restore to a cascaded clone target. For example, devices in an A -> B -> C cascaded clone session can copy data from device C to device A (through device B).

TimeFinder clone Persistent Restore to Target (restore Snap to Clone target)

Persistent Restore to Target (PTT) allows you to perform a TimeFinder/Snap restore to a TimeFinder/Clone target. For example, devices in an A -> B -> C cascaded session (where A -> B is TimeFinder/Clone and B -> C is TimeFinder/Snap) can copy data from device C to device A (via device B).

This operation can be performed without terminating the TimeFinder/Clone session or any existing TimeFinder/Snap sessions off of the TimeFinder/Clone target. PTT is supported in environments running Enginuity 5876.159.102 and higher with Solutions Enabler version 7.5 and higher.

TimeFinder cascaded clone configuration rules

When using a clone from a clone target, the following rules apply:

- If the session state is CopyInProg, SyncInProg or RestoreInProg, the -symforce flag is required.
- The Recreate and incremental clone establish commands are allowed only on differential sessions.
- The mode nocopy can only be set on nondifferential sessions.
- The mode precopy can only be set in created and recreated states.
- Enginuity 5876 only allows a 2 hop (device A -> target device B -> target device C) cascaded relationship provided the following interactions rules are followed. Any attempt to establish a 3 hop relationship (D -> C when A -> B -> C or Z -> A when A -> B -> C) will fail. Although circular cascading A -> B -> A is not allowed, devices A and B can have additional multiple targets. For example: A -> B(1) -> C(1) and A -> B(2) and A -> B(3) -> C(2). With two separate clone pairs like A-B and C-D, Enginuity 5876 allows a create, full establish, or full restore between B and C.

The table below lists the configuration rules for using a clone from a clone target. The terminate and cancel operations are allowed for all session states.

Table 5. Clone from clone target session states (both sessions are cascaded clone)

| B→C session | Clone A \rightarrow Clone B \rightarrow Clone Csession state |
|-------------|--|
| state | |

| | A→B | A→B | A→B | A→B | A→B | A→B | A→B |

Table 5. Clone from clone target session states (both sessions are cascaded clone) (continued)

Cascaded clone with VP Snap

Cascaded clone is supported with VP Snap with the following restrictions:

- Clone sessions must be in the Copied or Split state before you can create a VP Snap session from the target device.
- Incremental restore of VP Snap sessions is not permitted.
- The clone session must exist before the target device is used as a VP Snap source. Creating a clone session using a VP Snap source as the target device is not permitted.
- The target of a VP Snap session cannot be used as the source for any other clone or snap session.
- VP Snap is not supported with Clone Emulation mode.

VP Snap Restore to Target

VP Snap Restore to Target (VRTT) allows you to perform a VP Snap restore to a TimeFinder/Clone target. For example, devices in an A -> B -> C cascaded session (where A -> B is TimeFinder/Clone and B -> C is VP Snap) can copy data from device C to device A (via device B). VRTT is supported in environments running Enginuity 5876.159.102 with Solutions Enabler version 7.5.

Using a BCV as the clone source

As Creating a TimeFinder/Clone from a BCV source on page 37 shows, you can create a copy session between a BCV device and a target device. The controlling host performs I/O to the standard device that is established with a BCV as part of a BCV pair. At some point, when the BCV is synchronized with the standard device, you can split the BCV from the standard and create a copy session between the BCV and a target device that might be accessed by Host C. The split operation must be entirely complete, including the background phase, before you can create a copy session on it.

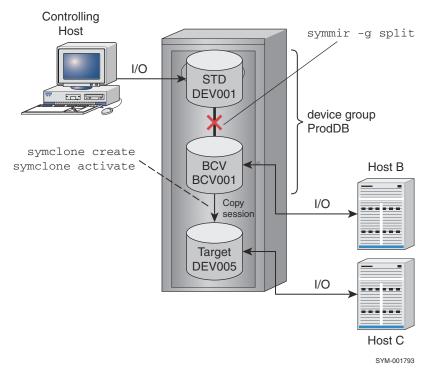

Figure 3. Creating a TimeFinder/Clone from a BCV source

For additional information on using the **symmir** command and how to perform an instant split operation, refer to TimeFinder/ Mirror Operations on page 94.

Pair states ruling clone operations

Because various other ongoing operations can conflict with a clone session, certain rules must be considered. The availability of some clone copy operations depends on the current state of SRDF and BCV pairs. The following rules apply to certain BCV pair states:

- If the source or target of a symclone create or activate operation is a BCV, the BCV pair state must be split. The split must be totally complete before the operation is allowed.
- Available with Enginuity 5876, a source device A to a target device B (BCV device) clone session is in Emulation Mode state and the source device B to target device C is a clone session.
- A TimeFinder standard device cannot be created or activated in a clone session if the BCV pair state is *SplitBfrRest* or *RestInProg*.
- The symclone terminate command is allowed for all TimeFinder pair states.
 (i) NOTE:

TimeFinder State Rules Reference on page 160 explains the TimeFinder pair states that apply to TimeFinder/Clone copy sessions. State rules for TimeFinder/Clone operations on page 196 contains specific information regarding possible SRDF pair state conflicts.

Example: Creating a clone from a source device

About this task

The following example creates a copy session between source device **BCV001** in device group **ProdDB** and target device DEV005 on the same array.

Once the copy session is activated, Host C can access target device tracks. If the accessed target tracks have not yet been copied, Enginuity software copies them for immediate access for Host C. If Host B writes to BCV device tracks that have not yet been copied, the Enginuity software immediately copies the tracks before allowing new data to overwrite those BCV tracks.

(i) NOTE:

In this example, where multiple hosts have access to the BCV source, consider using the -not_ready option with the **split** command to make the BCV not ready. This keep the same data on the BCV and clone. If you decide to use this option, you may need to release any Not Ready state imposed on any devices once the session completes.

The following steps outline the example shown in Creating a TimeFinder/Clone from a BCV source on page 37:

Steps

1. Perform an instant split on the BCV pair. Use the -not_ready option to prevent the BCV's host from writing to it prior to the clone operation:

symmir -g ProdDB split DEV001 -not_ready -noprompt

2. Verify that the background split is complete. The following command does a check every 5 seconds:

symmir -g ProdDB verify DEV001 -split -bg -i 30

3. Begin a copy session between the BCV source device **BCV001** and the standard target device **DEV005**:

symclone -g ProdDB create BCV001 sym ld DEV005

4. Activate the copy session to Host C:

symclone -g ProdDB activate BCV001 sym ld DEV005

5. Make the BCV device ready to its host:

symdg -g ProdDB ready -bcv BCV001 -noprompt

6. Query the state of the copy session and verify the CopyInProg state:

symclone -g ProdDB query

symclone -g ProdDB verify BCV001 -copyinprog

7. When the application has finished accessing the data, the copy session and pair relationship can be terminated:

symclone -g ProdDB terminate BCV001 sym ld DEV005 -noprompt

8. Incrementally reestablish the BCV pair:

symmir -g ProdDB establish DEV001 -noprompt

Creating multiple clone copies from a standard device

Creating multiple clone copies from a standard device on page 39 illustrates creating multiple clone copies from a standard source device **DEV001** on four standard target devices (**DEV005**, **DEV006**, **DEV007**, and **DEV008**) with various hosts accessing them.

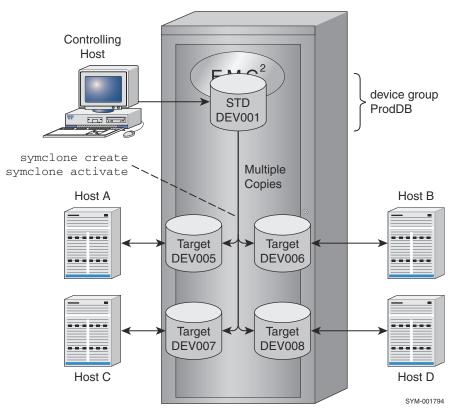

Figure 4. Creating multiple clone copies from a standard device

(i) NOTE:

A separate copy session must be created between the source device (**DEV001**) and each target device (**DEV005**, **DEV006**, **DEV007**, and **DEV008**).

Cloning a copy on a remote array

This section explains how to use SRDF to clone devices on a remote array.

() NOTE:

Refer to the EMC Solutions Enabler SRDF Family Version CLI User Guide for details about which SRDF features are supported with your platform.

Cloning a local R1 standard device

About this task

Cloning a copy of a local R1 standard device on a remote array on page 40 illustrates how to clone a copy of a local R1 standard device on a remote array. Performing SYMCLI commands from the controlling host allows the remote target device to receive a copy of the data from the R2 device. The cloned data can be accessed by the remote host.

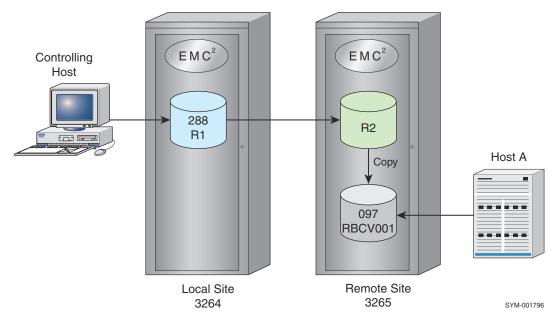

Figure 5. Cloning a copy of a local R1 standard device on a remote array

The following steps outline the example shown in Cloning a copy of a local R1 standard device on a remote array on page 40:

Steps

1. Create an RDF1 type device group:

```
symdg create Rdf1Grp -type rdf1
```

2. Add to the device group an R1 standard device (288) on the local array (sid 3264) to be the source device. Associate a target BCV device (097) on the remote array to hold the clone copy. Note that to perform a remote operation you will need to use a remote target list (RTGT or RBCV list). This example uses an RBCV list.

symdg -g RdflGrp -sid 3264 add dev 288 symbcv -g RdflGrp associate dev 097 -rdf

3. Clone an immediate full copy from the source device (DEV001) to the remote BCV target device (RBCV001). DEV001 is the logical device name for device 288, and RBCV001 is the logical device name for BCV 097:

symclone -g Rdf1Grp establish -full DEV001 bcv ld RBCV001 -rdf

4. To query the progress of the clone operation or verify when the copy is completed, issue the following commands that examine the clone pair (source and target):

symclone -g RdflGrp query -rdf symclone -g RdflGrp verify -copied -rdf

Cloning a copy of a local BCV device on a remote array

About this task

Cloning a copy of a local BCV device on a remote array on page 41 illustrates how to clone a copy of a local BCV device on a remote array. Performing SYMCLI commands from the controlling host allows the remote target device to receive a copy of the data from the R2 device. The cloned data can be accessed by remote Host A.

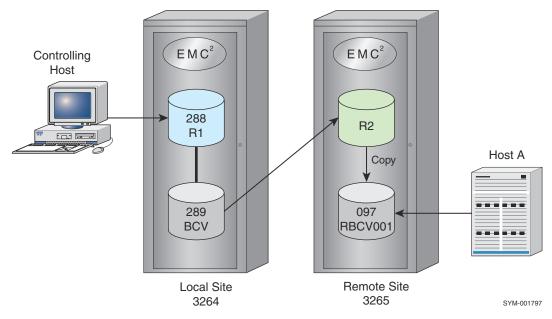

Figure 6. Cloning a copy of a local BCV device on a remote array

The following steps outline the example shown in Cloning a copy of a local BCV device on a remote array on page 41:

Steps

1. Create an RDF1 type device group:

symdg create Rdf1Grp -type rdf1

Add to the device group a BCV device (289) on the local array (-sid 3264) to be the source device. Associate a target BCV device (289) on the local array. Associate a target BCV device (097) on the remote array to hold the clone copy. In this case, the remote target device must be a BCV:

```
symdg -g RdflGrp -sid 3264 add dev 288
symbcv -g RdflGrp -sid 3264 associate dev 289 -rdf
symbcv -g RdflGrp associate dev 097 -rdf
```

 Clone an immediate full copy from the BCV device (BCV001) to the remote BCV target device (RBCV001). DEV001 is the logical device name for device 288, and RBCV001 is the logical device name for BCV 097:

symclone -g Rdf1Grp establish -full BCV001 bcv ld RBCV001 -rdf -bcv

4. To query the progress of the clone operation or verify when the copy is completed, issue the following commands that examine the clone pair (source and target):

```
symclone -g Rdf1Grp query -rdf -bcv
```

symclone -g Rdf1Grp verify -copied -rdf -bcv

Cloning a copy on a hop-2 array

About this task

Cloning a copy of a local R1 standard device on a Hop-2 array on page 42 illustrates how to clone a copy of a local R1 standard device on a remote array in the second level of a multihop environment. Performing SYMCLI commands from the controlling

host allows the remote target device to receive a copy of the data from the R2 device. The cloned data can be accessed by remote Host A.

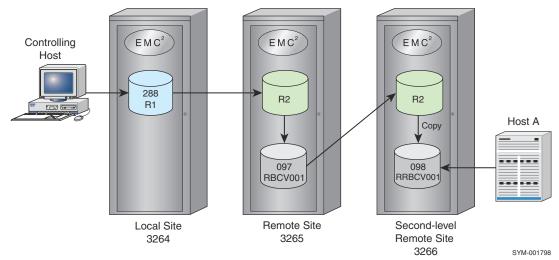

Figure 7. Cloning a copy of a local R1 standard device on a Hop-2 array

The following steps outline the example shown in Cloning a copy of a local R1 standard device on a Hop-2 array on page 42:

Steps

1. Create an RDF1 type device group:

```
symdg create Rdf1Grp -type rdf1
```

2. Add to the device group an R1 standard device (288) on the local array (-sid 3264) to be the source device. Associate a BCV device (097) on the Hop-1 array. Associate a BCV device (098) on the second-level (Hop-2) remote array to hold the clone copy. To perform a remote operation, you must use a remote target list (RTGT or RBCV list). Our example uses an RBCV list:

```
symdg -g Rdf1Grp -sid 3264 add dev 288
symbcv -g Rdf1Grp associate dev 097 -rdf
symbcv -g RDF1GRP associate dev 098 -rrdf
```

 Clone an immediate full copy from the source device (DEV001) to the remote BCV target device (RRBCV001). DEV001 is the logical device name for device 288, and RRBCV001 is the logical device name for BCV 098:

symclone -g Rdf1Grp establish -full RBCV001 bcv ld RRBCV001 -rrbcv

Instead of specifying the device level, you can also specify the device group:

symclone -g Rdf1Grp establish -full -rrbcv

4. To query the progress of the clone operation or verify when the copy is completed, you can issue the following commands that examine the clone pair (source and target):

symclone -g Rdf1Grp query -rrbcv

symclone -g Rdf1Grp verify -copied -rrbcv

Cloning copies of the same data locally and remotely

About this task

Copies of the same data can be cloned to devices on a local and remote array at the same time so that their target devices have the same originator data.

Note that in the examples that follow, the procedures are very similar. The only differences are the device types used for the local copy (local target and local BCV target) and the command arguments used for the respective device type.

Example 1

Cloning copies of a local R1 standard to a local target and to a remote BCV target on page 43illustrates how you can clone copies of a local R1 standard device to a local target device and to a remote BCV target device on a remote array.

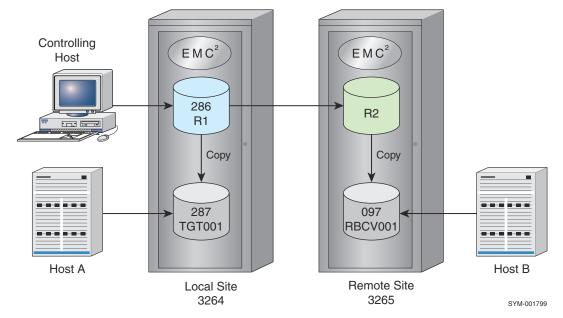

Figure 8. Cloning copies of a local R1 standard to a local target and to a remote BCV target

Steps

1. Create an RDF1 type device group:

```
symdg create Rdf1Grp -type rdf1
```

2. Add to the device group an R1 standard device (286) on the local array (-sid 3264) to be the source device. Add a standard device target (287) on the local array. Associate a remote BCV target (097) on the remote array. To perform a remote operation, you must use a remote target list (RTGT or RBCV list). This example uses an RBCV list:

```
symdg -g RdflGrp -sid 3264 add dev 286
symdg -g RdflGrp -sid 3264 add dev 287
symbcv -g RdflGrp associate dev 097 -rdf
```

3. Clone an immediate full copy from the source device (DEV001) to the local and remote target devices (DEV002 and RBCV001, respectively). If there is no I/O to the source R1 device between these two commands, the same data will exist on both the local and remote target devices:

symclone -g RdflGrp establish -full symclone -g RdflGrp establish -full -rdf **4.** To query the progress of the local clone operation or verify when the local copy is completed, you can issue the following commands that examine the local cloned pair (source and target):

```
symclone -g Rdf1Grp query
symclone -g Rdf1Grp verify -copied
```

5. To query the progress of the remote clone operation or verify when the remote copy is completed, you can issue the following commands:

```
symclone -g RdflGrp query -rdf
symclone -g RdflGrp verify -copied -rdf
```

Cloning copies of a local device to a local BCV target and to a remote BCV target on page 44 illustrates how to clone copies of a local R1 standard device to a local BCV target device and to a BCV target device on a remote array.

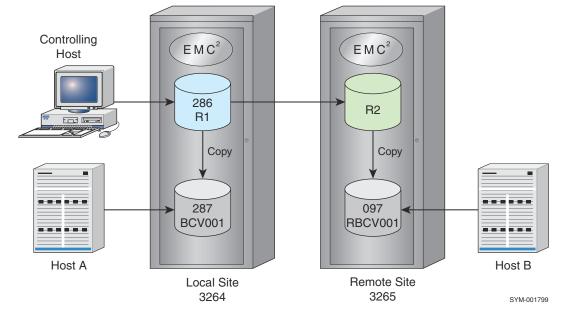

Figure 9. Cloning copies of a local device to a local BCV target and to a remote BCV target

6. Create an RDF1 type device group:

```
symdg create Rdf1Grp -type rdf1
```

7. Add to the device group an R1 standard device (286) on the local array (-sid 3264) to be the source device. Add a BCV target (287) on the local array. Associate a remote BCV target (097) on the remote array. To perform a remote operation, you must use a remote target list (RTGT or RBCV list). This example uses an RBCV list:

```
symdg -g RdflGrp -sid 3264 add dev 286
symdg -g RdflGrp -sid 3264 add dev 287 -tgt
symbcv -g RdflGrp associate dev 097 -rdf
```

8. Clone an immediate full copy from the source device (DEV001) to the local and remote target devices (BCV001 and RBCV001, respectively). If there is no I/O to the source R1 device between these two commands, the same data will exist on both the local and remote target devices:

```
symclone -g Rdf1Grp establish -full -tgt
symclone -g Rdf1Grp establish -full -rdf
```

9. To query the progress of the local clone operation or verify when the local copy is completed, you can issue the following commands that examine the local cloned pair (source and target):

```
symclone -g RdflGrp query
symclone -g RdflGrp verify -copied
```

10. To query the progress of the remote clone operation or verify when the remote copy is completed, you can issue the following commands:

```
symclone -g RdflGrp query -rdf
symclone -g RdflGrp verify -copied -rdf
```

Cloning multiple copies locally and remotely

Multiple copies of the same data can be cloned to devices on a local and remote array at the same time so that their target devices have the same originator data.

The configuration in Cloning multiple copies on local and remote arrays on page 45 is basically the same as the configuration in Cloning copies of a local R1 standard to a local target and to a remote BCV target on page 43 and Cloning copies of a local device to a local BCV target and to a remote BCV target on page 44 except that this configuration uses a single symclone command to clone copies from a source device to four target devices on each array instead of cloning copies to one target on each array. In this configuration, eight hosts have access to copies of the same target data.

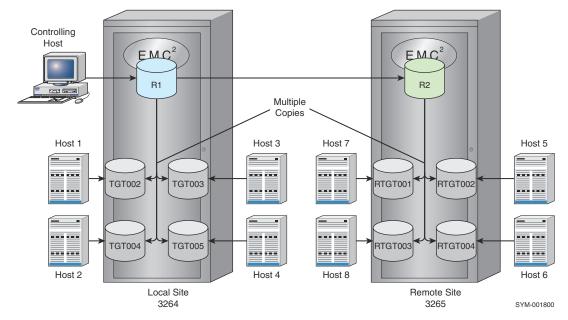

Figure 10. Cloning multiple copies on local and remote arrays

The process for building an RDF1 type device group is similar to the previous section. To add a source standard R1 device, a range of four standard device targets from the local array, and a range of four targets from the remote array:

```
symdg -g Rdf1Grp -sid 3264 add dev 100
```

symdg -g Rdf1Grp addall -devs 101:104 -tgt -sid 3264

symdg -g Rdf1Grp addall -devs 214:218 -rdf -tgt -sid 3265

What is different about this configuration is the cloning of copies from a single source to multiple target devices. To clone the four local target devices (TGT002, TGT003, TGT004, and TGT005) from the local source device (DEV001), you need to issue four symclone establish commands, specifying the same source device with each of the four targets:

symclone -g Rdf1Grp establish -full DEV001 sym ld TGT002

symclone -g Rdf1Grp establish -full DEV001 sym ld TGT003

symclone -g Rdf1Grp establish -full DEV001 sym ld TGT004

symclone -g Rdf1Grp establish -full DEV001 sym ld TGT005

To display the progress of all devices involved in the local clone operation, perform a clone query with the -multi option:

symclone -g Rdf1Grp query -multi

To verify the clone completion of one or more clone pairs in the device group specifically, or all clone devices, enter:

symclone -g Rdf1Grp verify -copied DEV001 sym 1d DEV002

symclone -g Rdf1Grp verify -copied

To clone the four remote target devices (RTGT001, RTGT002, RTGT003, and RTGT004) from the source device (DEV001), issue four symclone establish commands with the -rdf option:

symclone -g Rdf1Grp establish -full -rdf DEV001 bcv ld RTGT001

symclone -g Rdf1Grp establish -full -rdf DEV001 bcv ld RTGT002

symclone -g Rdf1Grp establish -full -rdf DEV001 bcv ld RTGT003

symclone -g Rdf1Grp establish -full -rdf DEV001 bcv ld RTGT004

To display the progress of all devices involved in the remote clone operation, perform a clone query with the -multi option and the -rdf option:

symclone -g Rdf1Grp query -multi -rdf

To verify the clone completion of one or more remote clone pairs in the device group specifically, or all remote clone devices, add the -rdf option:

symclone -g Rdf1Grp verify -copied -rdf DEV001 sym ld RTGT004

symclone -g Rdf1Grp verify -copied -rdf

Cloning a copy at the tertiary site of a cascaded SRDF configuration

About this task

Using SRDF technology and the TimeFinder hop2 flag (-hop2 option), you can clone devices on an array located at the tertiary site of a cascaded SRDF configuration on page 47). Performing SYMCLI commands from the controlling host allows the tertiary target device to receive a copy of the data from the R2 device. The cloned data can be accessed by remote Host A.

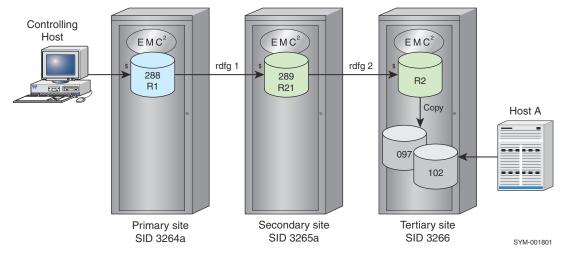

Figure 11. Cloning a copy at the tertiary site of a cascaded SRDF configuration

The following steps outline an example of cloning devices on an array located at the tertiary site of a cascaded SRDF configuration:

(i) NOTE:

The following procedure provides examples of device group and composite group commands.

Steps

1. Create an RDF1-type device group or composite group (for example, a group named RDF1Grp):

To create an RDF1-type device group:

symdg create Rdf1Grp -type rdf1

To create an RDF1-type composite group:

symcg create Rdf1Grp -type rdf1

2. Add devices to the group. From the primary site array, add an R1 standard device to be the source device. From the tertiary site array, add a target BCV device (097) to hold the clone copy:

To add devices to a device group:

```
symdg -g Rdf1Grp -sid 3264 add dev 288
symbcv -g Rdf1Grp -hop2 -rdfg 1 -remote_rdfg 2 add dev 097
```

To add devices to a composite group:

symcg -cg RdflGrp -sid 3264 add dev 288 symbcv -cg RdflGrp -sid 3264 -hop2 -rdfg 1 -remote_rdfg 2 add dev 097 To add target devices to a device group using the -tgt option: symdg -g RdflGrp -hop2 -rdfg 1 -remote_rdfg 2 -tgt add dev 102 To add devices to a composite group using the -tgt option: symbcv -cg RdflGrp -sid 3264 -hop2 -rdfg 1 -remote_rdfg 2 -tgt add dev 102

3. Clone an immediate full copy from the source device to the remote BCV target device:

symclone -g Rdf1Grp -hop2 create -precopy

Or, you can use the -tgt option:

symclone -g RdfGrp1 -hop2 create -precopy -tgt

4. To query the progress of the clone operation or verify when the copy is completed, you can issue the following commands that examine the clone pair (source and target):

symclone -g Rdf1Grp query -hop2

symclone -g Rdf1Grp verify -copied -hop2

Using composite groups to manage clone pairs across arrays

About this task

Using a composite group when a set of devices spans two arrays on page 49 shows a production host locally connected to two arrays (A and B). A composite group is defined on the production host and includes source devices and target devices from each array. The target devices can be standard devices or BCV devices. Another locally connected host allows access to the clone targets.

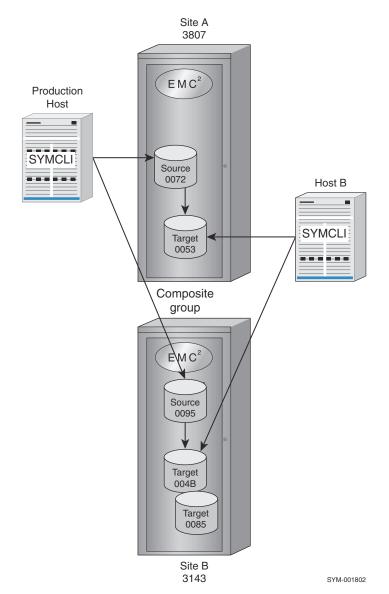

Figure 12. Using a composite group when a set of devices spans two arrays

Although clone copy operations might normally be performed from the production host (Using a composite group when a set of devices spans two arrays on page 49) because the composite group is defined there in its SYMAPI database, there are methods that would allow you to control clone operations from another locally connected host like the target host. One way is to copy the composite group definition to another host. A more efficient method is to enable Group Naming Services (GNS), which automatically propagates the composite group definition to the arrays and other locally attached hosts that are running the GNS daemon.

The following steps explain how to setup a composite group that spans two arrays as shown in Using a composite group when a set of devices spans two arrays on page 49:

Steps

1. From the production host, create a Regular type composite group (for example, MyGrp):

```
symcg create MyGrp -type regular
```

2. Add to the composite group those standard devices on array A (3087) and array B (3143) that are the source devices:

symcg -cg MyGrp -sid 3087 add dev 0072

symcg -cg MyGrp -sid 3143 add dev 0095

3. Associate a BCV target device from each array with the composite group:

symbov -cg MyGrp -sid 3087 associate dev 0053

4. Create clone pair sessions from those devices in the composite group:

symclone -cg MyGrp create

5. Activate these clone pair sessions:

symclone -cg MyGrp activate

Once you have setup the composite group, you can control specific clone pairs within it, as long as the devices reside in the same array. To create and activate only the DEV001 and DEV002 clone pair from all devices in the group:

symclone -cg MyGrp create DEV001 sym ld DEV002

symclone -cg MyGrp activate DEV001 sym 1d DEV002

Or using the one-step method:

symclone -cg MyGrp establish -full DEV001 sym ld DEV002

Command options with device groups

symclone -g control arguments and possible options on page 50 lists the **symclone** control operations and the possible options to use when targeting a specified device group.

Table 6. symclone -g control arguments and possible options

TimeFinder/Snap Operations

This chapter describes how to control copy sessions for virtual devices using the SYMCLI **symsnap** command.

Topics:

- TimeFinder/Snap overview
- Creating a virtual copy session
- Activating a virtual copy session
- Recreating a virtual copy session (Enginuity 5876)
- Restoring data from virtual devices
- Terminating a virtual copy session
- Querying snap pairs
- Verifying snap pair states
- Using a BCV as the snap source
- Creating multiple virtual copies
- Attaching source and target virtual devices
- Using composite groups to manage snap pairs across arrays
- Snapping a copy on a remote array
- Snapping a copy from a remote BCV
- Snapping copies of a source device's data locally and remotely
- Snapping multiple copies
- Snapping a copy at the tertiary site of a cascaded SRDF configuration
- Snapping a copy from a clone target device
- Command options with device groups or composite groups
- Command options with device files

TimeFinder/Snap overview

For a high-level overview of TimeFinder/Snap functionality, refer to the EMC Symmetrix TimeFinder Product Guide.

() NOTE:

TimeFinder/Snap is not supported on the VMAX 10K platform. Refer to your product guide for details about supported features.

Snap operations are controlled from the host by using the **symsnap** command to **create**, **activate**, **terminate**, and **restore** the snap copy sessions. The snap operations described in this chapter explain how to manage the devices participating in a copy session using the SYMCLI.

() NOTE:

Data domain devices are not supported as TimeFinder/Snap source or target devices.

Copy of a standard device to a virtual device (VDEV) on page 58 illustrates a virtual copy session where the controlling host creates a copy of standard device **DEV001** on target device **VDEV005**.

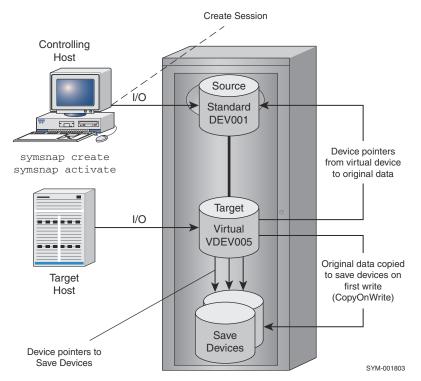

Figure 13. Copy of a standard device to a virtual device (VDEV)

Creating a virtual copy session

Initially, you must create a virtual copy session that defines and sets up the snap devices you have selected for the snap operation. For example, to begin a copy session and define a specified target device VDEV005 to be the copy of source device DEV001 in group **ProdDB**, enter:

symsnap -g ProdDB create DEV001 vdev ld VDEV005

The **symsnap** create action defines the copy session requirements and sets the track protection bitmap on the source device to protect all tracks and detect which tracks are being accessed by the target host or written to by the source host. The target virtual device remains Not Ready to its host and placed on hold status for copy session usage.

This prevents other control operations from using the device. The device pair state will transition from CreatelnProg to Created when complete. The virtual data becomes accessible to its host when the copy session is activated. Refer to Activating a virtual copy session on page 60 for more information.

Copy Session Limits on page 16 provides details about the number of virtual copy sessions that you can create.

Multivirtual snaps

With multivirtual snaps enabled, Solutions Enabler supports up to 128 snaps from a source device. This support requires that you enable the following SYMCLI environment variable:

```
SYMCLI MULTI VIRTUAL SNAP = ENABLED
```

() NOTE:

TimeFinder/Snap sessions on VMAX 40K systems always use multi-virtual mode regardless of how this variable is set.

This setting appears in the snap device output from symdev show. The Snap State Flags value will be MultiVirtual.

A single source device can only have snaps of one type.

The SYMCLI Auto Terminate policy does not apply to multivirtual snaps. Even if the SYMCLI_SNAP_PAIR_POLICY environment variable is set to TERM_OLDEST, you cannot create a new multivirtual snap session after the maximum number of sessions has been reached.

() NOTE:

Starting with Enginuity 5876.159.102, multivirtual snap operations are supported with CKD devices. Snap **recreate** for multivirtual snap operations is supported in environments running Enginuity 5876.

Specifying a SAVE device pool

VMAX supports the creation of multiple named SAVE device pools, allowing symsnap commands to use a particular pool.

The -svp option can be used with the create action to specify which SAVE device pool to use for an operation. For example, to instruct the copy session created in the example on Creating a virtual copy session on page 58 to use the SAVE device pool Accounting, use the following **symsnap** command:

symsnap -g ProdDB create DEV001 vdev ld VDEV005 -svp Accounting

() NOTE:

The specified pool must exist and contain at least one enabled device before creating the copy session.

In addition to the -svp option, you can also set the environment variable SYMCLI_SVP to a poolname to be used when -svp is not present in the command line. If -svp and SYMCLI_SVP are not used, the operation will use the default pool, DEFAULT_POOL.

() NOTE:

SAVE devices can also be organized into Delta Set Extension pools for use with SRDF/A. Refer to the EMC Solutions Enabler SRDF Family CLI User Guide for more information on using SAVE devices in this way.

Monitoring SAVE device usage

Using virtual copies requires proper planning to prevent the SAVE devices from filling up with pre-updated data. If the SAVE devices fill up, you will begin to lose the pre-update images of the newly changed tracks in the virtual copy session, the virtual device will be set to Not Ready, and the session will fail (only sessions with I/O activity will be in a failed state, sessions without I/O activity will continue to operate normally).

Should this happen, you must terminate the failed sessions to clear the tracks on the SAVE devices. Once a session is terminated, the virtual data is lost and the SAVE device space associated with the session is freed and returned to the SAVE device pool for TimeFinder/Snap use. In addition, you should also examine how you are using the SAVE device pools and consider adding more SAVE devices.

You can monitor SAVE devices by using the symcfg show command to display SAVE device pool details. For more information, refer to the EMC Solutions Enabler Array Management CLI User Guide.

Pairing an additional target device with each source device in a group

When working with either a composite or device group, you can use the -concurrent option with the create action to pair an additional target device with each source device in a group.

To pair an additional target device with each source device in group ProdDB, enter:

symsnap -g ProdDB create -concurrent

When the copy session is created, an additional target device will be paired with each source device in the group. For example, if there were two target devices paired with each source device in the group before activating the session, there will be three target devices paired with each source device after the session is activated.

To verify that each source device in the group has multiple targets, enter:

symsnap -g ProdDB verify -created -concurrent

Copying a virtual device to another virtual device (duplicate snap)

Duplicate snap functionality, supported with (Enginuity 5876, allows you to duplicate a point-in-time copy of a virtual device, which is paired in a previously activated snap session, to another virtual device. This second point-in-time copy session resides with the source device of the original snap session and is charged as part of the maximum number of sessions for that source device.

Use the -duplicate option with the -create command to begin a copy session that will take one or more source virtual devices and create a copy of the point-in-time data to one or more target virtual devices. For example, to begin a copy session and define virtual device VDEV002 to be the copy of source device VDEV001 in group **ProdDB**, enter:

symsnap -g ProdDB create -duplicate VDEV001 vdev ld VDEV002

In this example, VDEV001 is the target of an activated snap session and VDEV002 is not snap paired. The resulting duplicate session is the same point-in-time as the original virtual device, but the time stamp is not inherited from the original virtual device's session. The newly created session has its own time stamp indicating the time of its creation.

The following restrictions apply to the duplicate snap functionality:

- Snap create and activate operations cannot be mixed between normal snap sessions and duplicate snap sessions within the same operation.
- Two is the maximum number of duplicated sessions in the Created state.
- When a duplicate snap session is in the Created state, the original session cannot be terminated or recreated until the duplicate session is activated.

Activating a virtual copy session

To create a point-in-time image, you must activate the create copy session. To activate the copy session created in the example in Creating a virtual copy session on page 58, use the following symsnap command:

symsnap -g ProdDB activate DEV001 vdev ld VDEV005

This activates the copy operation from the source device to the virtual target device. Activating the copy session starts the copy on first write mechanism and places the target device in the Read/Write state. The target host can access the copy and has access to data on the source host until the copy session is terminated.

() NOTE:

Virtual data is made available as a point-in-time copy at the time of activation and not at the time that the session was created.

Using the establish command

With Solutions Enabler 7.4 and higher, you can use the symsnap establish command to create and then immediately activate a copy session with a single command.

To create and then activate the copy session shown in the example in Creating a virtual copy session on page 58, enter:

symsnap -g ProdDB establish DEV001 vdev ld VDEV005 -full

Making the target device not ready to the host

The Not Ready (-not_ready) option can be used with the **activate** action to start the CopyOnWrite mechanism but causes the target device to remain not ready to its host, as follows:

symsnap -g ProdDB activate DEV001 vdev ld VDEV005 -not_ready

The copy session will be activated and the target device will be placed in the Not Ready state. The snap copy can later be Read/Write enabled to the host using the symdg ready command.

Activating copy sessions consistently

You can consistently activate multiple virtual copy sessions involving a database using the Enginuity Consistency Assist (ECA) feature. These features allow snap copy sessions to be activated with a consistent, restartable copy of the database.

Using ECA

You can use the Enginuity Consistency Assist (ECA) feature to activate virtual copy sessions that are consistent with the database up to the point in time that the activation occurs. The feature suspends writes to the source device during the activation.

Use the symsnap activate command with the consistent (-consistent) option to invoke ECA. When the activation has completed, writes are resumed and the target device contains pointers for a consistent production database copy of the source device at the time of activation.

To consistently activate copy sessions using ECA, you must have either a control host with no database or a database host with a dedicated channel. This will ensure that in write intensive environments SYMAPI will be able to activate the copy sessions within the ECA window, regardless of the number of outstanding I/Os held by the HBA. Refer to TF/Snap consistent activate using ECA on page 62, for a depiction of how a control host can consistently activate a copy session involving three database hosts that access devices on an array.

A device group, composite group, or a device file must be created on the controlling host for the target database to be consistently activated. Device groups can be created to include all of the devices being accessed or defined by database host access. For example, if you define a device group that includes all of the devices being accessed by Hosts A, B, and C (TF/Snap consistent activate using ECA on page 62), then you can consistently activate all of the copy sessions related to those hosts with a single command. However, if you define a device group that includes only the devices accessed by Host A, then you can activate those copy sessions related to Host A without affecting the other hosts.

() NOTE:

When activating a copy session from an R2 device, if the SRDF pair is in adaptive copy mode, the -consistent option is not allowed.

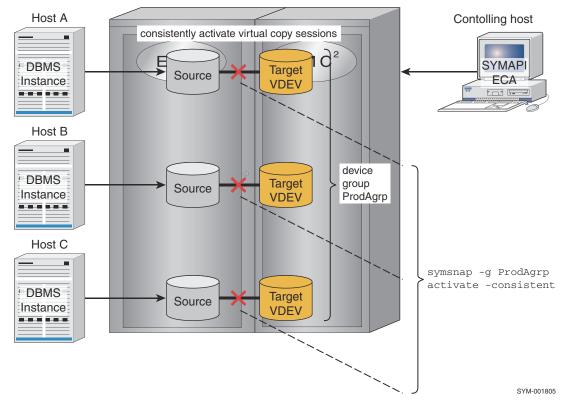

Figure 14. TF/Snap consistent activate using ECA

Activating an additional copy session for each device pair in a group

When working with either a composite or device group, you can use the -concurrent option with the **activate** action to activate an additional copy session for each device pair in a group.

To activate an additional copy session for each device pair in group ProdDB, enter:

```
symsnap -g ProdDB activate -concurrent
```

Activating a duplicate snap session

Once a duplicate snap session is activated, the copied session works like a normal snap session between the original source device and the duplicated virtual device. This session may be used for restore, recreate, and terminate operations.

Use the -duplicate option with the -activate command to activate a duplicate snap session. For example, to activate the copy session between target device VDEV002 and source device VDEV001 in group ProdDB, enter:

symsnap -g ProdDB activate -duplicate VDEV001 vdev ld VDEV002

In this example, the result is an activated session between DEV001 and VDEV002, which is in addition to the original session between DEV001 and VDEV001.

Combining the create and activate commands for a duplicate snap

You can combine the symsnap create -duplicate and symsnap activate -duplicate commands into a single action by using the **symsnap duplicate** command. For example, to create and activate a copy session between target device VDEV002 and source device VDEV001 in group ProdDB, enter:

symsnap -g ProdDB duplicate VDEV001 vdev ld VDEV002

Recreating a virtual copy session (Enginuity 5876)

Snap sessions can be recreated on an existing virtual device (VDEV) in preparation of activating a new point-in-time image. Snap recreate is only valid when issued against sessions that have been previously activated. This process makes it more convenient to reuse a virtual device to acquire a new point-in-time image. This feature is supported with Enginuity 5876.

Since the **recreate** operation replaces the previous point-in-time image with a new one, the used tracks in the SAVE devices that were associated with the previous session are freed during the processing of this command.

Recreating a virtual snap copy session requires the following steps:

- 1. Create a snap session. (Refer to Recreating a virtual copy session (Enginuity 5876) on page 63.)
- 2. Activate a snap session. (Refer to Activating a virtual copy session on page 60.)
- 3. Recreate a snap session.
- 4. Activate a snap session. (Refer to Activating a virtual copy session on page 60.)
- 5. Repeat the recreate/activate a snap session, as necessary.
- 6. Terminate the snap session when no longer needed. (Refer to Terminating a virtual copy session on page 66.)

To recreate the copy session activated in the example on Activating a virtual copy session on page 60 use the following symsnap command:

symsnap -g ProdDB recreate DEV001 vdev ld VDEV005

With Solutions Enabler 7.4 and higher, you can use the symsnap establish command to recreate and then immediately activate a copy session with a single command.

To combine steps 3 and 4 described above, enter:

symsnap -g ProdDB establish DEV001 vdev ld VDEV005

The snap recreate functionality is supported with the symsnap query and symsnap verify commands. For example:

symsnap -g TestDg query -multi

symsnap -g TestDg verify -recreated

() NOTE:

You can use the **-recreated** parameter in combination with other verify states when verifying for multiple states. When multiple verify states are listed, the states are evaluated in a logical OR fashion so the result will be true if the session is in any of the listed states.

The following restrictions apply to the snap recreate functionality:

- The session to be recreated must be in a CopyOnWrite or Copied state.
- Any restore session that exists on the device must be terminated prior to issue the recreate operation.
- Snap recreate for multivirtual snap operations is supported in environments running Enginuity 5876.

Restoring data from virtual devices

Three types of restore operations can be performed for virtual device copy sessions:

- Incremental restore back to the original source device.
- Incremental restore to a BCV, which has been split from its original standard source device but maintains the incremental relationship with the source.
- Full restore to any standard or split BCV device outside of the existing copy session. The target device of the restore must be of the same size and emulation type as the source device.

A new restore copy session between the source device and the restore target device is created. A restore operation can only be performed if an additional copy session (two for Enginuity 5876) is available for use.

By default, any existing copy sessions persist until manually terminated by using the symsnap terminate command. After the virtual device has been restored to another device, the restore copy session must be terminated first, before another

restore operation is allowed from that virtual device. Use the symsnap query -multi command to view all existing targets paired with a source device. The original snap copy session displays as being in the CopyOnWrite state, and the restore copy session displays as being either in the RestInProg or Restored state.

Incrementally restoring to a source

The following command-line entry shows an incremental restore operation back to the original source device DEV001 from the virtual device VDEV005:

```
symsnap restore DEV001 vdev ld VDEV005
```

In this example, through the use of device pointers to the SAVE device, the virtual device **VDEV005** will be incrementally restored back to **DEV001**. Any changes made to the virtual device tracks during the active copy session will be restored back to the original source device.

() NOTE:

Any changes written to the original source device during the copy session will be overwritten by the virtual device tracks when the source device is restored.

The restore target device (source device DEV001) and virtual device (VDEV005) are automatically set to the Not Ready state while the track protection bitmaps are set up to copy any changed tracks. DEV001 automatically becomes available for use (Ready state) as soon as the track protection bitmap completes. The changed tracks then begin copying and will continue to copy in the background until all the protected tracks have been restored.

If you want to continue using the original copy session, the virtual device must be manually set to the Ready state after the restore operation has completed (all tracks are copied back to the source). Use one of the following commands to set the virtual device to the Ready state after the above restore operation:

```
symdg -g Group1 ready -vdev VDEV005
symdev -sid SymmID ready 001C
```

Once the restore completes, both the original and restore copy sessions are maintained and must be terminated manually if not needed for future use. When a original session is terminated, the device pointers are deleted from the virtual device and the SAVE device space is freed for future use.

() NOTE:

The restored copy session must be terminated first, before the original copy session is allowed to be terminated.

To terminate the restored copy session, enter:

symsnap terminate DEV001 vdev ld VDEV005 -restored

To terminate the original copy session, enter:

```
symsnap terminate DEV001 vdev ld VDEV005
```

Incrementally restoring to a BCV

The following command-line entry shows an incremental restore operation to a split BCV device BCV001 from the virtual device VDEV005:

symsnap restore BCV001 vdev ld VDEV005

To restore to a BCV device, the BCV device must be split from its standard device. The point-in-time snap copy is restored to the BCV as shown in Incremental restore to a BCV on page 65. However, any further changes made to the point-in-time snap copy (from the attached host to the VDEV), during the active copy session, will also be included in the restore action to the split BCV device (BCV001). A new copy session begins between the source and target BCV and any changed tracks pointed to by the pointers are then copied to the split BCV from the source and SAVE devices. (Only the tracks that are different between

the BCV and VDEV are copied.) Once the restore completes, both the original and restore copy sessions are maintained until manually terminated.

Device pointers to Controlling source device Target Host B Host STD Target I/O I/OSource Virtual DEV001 /DEV005a --symsnap create DEV001 vdev 1d VDEV005 symsnap activate DEV001 vdev 1d VDEV005 T Device pointers BCV is split from its standard source to save devices Save BCV001 Devices Step 1 - Active Virtual Copy Session Original device pointers to source Controlling device are maintained. Host Host B STD Source Virtual DEV001 /DEV005a 2 symsnap restore BCV001 vdev ld VDEV005 ¥ 1 3 I. BCV is split from its (1)Original device pointers to Restore standard source save devices are maintained. Target Save BCV001 Devices (3) (1) Restore target inherits device pointers. VDEV copy session is maintained. The new copy session begins 2 between the source and target BCV. Changed tracks are then copied to the restore target from source and save devices. (3) Step 2 - Restore the Virtual Copy Session to BCV SYM-001804

(i) NOTE: You cannot restore to a BCV running in emulation mode.

Figure 15. Incremental restore to a BCV

The target device (BCV001) and the virtual device (VDEV005) are automatically set to the Not Ready state while the track protection bitmaps are set up to copy any changed tracks. **BCV001** automatically becomes available for use (Ready state) as soon as the track protection bitmap completes. The changed tracks then begin copying and will continue to copy in the background until all protected tracks have been restored.

If you want to continue using the original copy session, the virtual device must be manually set to the Ready state after the restore operation has completed (all tracks are copied to the split BCV). Use one of the following commands to set the virtual device to the Ready state after the above restore operation:

```
symdg -g Group1 ready -vdev VDEV005
```

```
symdev -sid SymmID ready 001D
```

() NOTE:

The restored copy session must be terminated first, before the original copy session is allowed to be terminated.

To terminate the restored copy session, enter:

symsnap terminate DEV001 bcv ld BCV001 -restored

To terminate the original copy session, enter:

symsnap terminate DEV001 vdev ld VDEV005

Optionally, after terminating the copy session, you can also issue a TimeFinder **symmir restore** operation from the restored BCV back to the standard source device. For information on reestablishing and restoring BCV pairs, refer to TimeFinder/Mirror Operations on page 94.

Fully restoring to anywhere

A full device restore operation from the virtual device is allowed to any device of the same size and emulation type as the source device. The following example uses the restore command with the -full option to fully restore a virtual device VDEV005 to another standard device DEV004:

symsnap -full restore DEV004 vdev ld VDEV005

Any changes made to the virtual device (VDEV005) during the active copy session will be restored to the specified device (DEV004). The restore target inherits the virtual device pointers. A new copy session begins between the source and target device and any changed tracks pointed to by the pointers are then copied to the target device from the source and SAVE devices. Upon completion of the restore operation, both the original and restore copy sessions are maintained until manually terminated.

The target device (DEV004) and the virtual device (VDEV005) are automatically set to the Not Ready state while the track protection bitmaps are set up to copy any changed tracks. **DEV004** automatically becomes available for use (Ready state) as soon as the track protection bitmap completes. The changed tracks then begin copying and will continue to copy until all protected tracks have been restored.

If you want to continue using the original copy session, the virtual device must be manually set to the Ready state after the restore operation has completed (all tracks are copied to the restore target). Use one of the following commands to set the virtual device to the Ready state after the above restore operation:

```
symdg -g Group1 ready -vdev VDEV005
symdev -sid SymmID ready 001E
```

When a session is terminated, all device pointers are deleted from the virtual device and the SAVE device space is freed for future use.

() NOTE:

The restored copy session must be terminated first, before the original copy session is allowed to be terminated.

To terminate the restored copy session, enter:

symsnap terminate DEV001 sym ld DEV004 -restored

To terminate the original copy session for a virtual device, enter:

```
symsnap terminate DEV001 vdev 1d VDEV005
```

Terminating a virtual copy session

To terminate the copy session activated in the example in Activating a virtual copy session on page 60 use the following **symsnap** command:

```
symsnap -g ProdDB terminate DEV001 vdev ld VDEV005
```

Terminating a copy session deletes the pairing information in the array and removes any hold on the target device. Terminating the session causes the target host to lose access to data pointed to by the virtual device.

Terminating a session while the device pairs are in the CopyOnWrite state will cause the session to end. Once the virtual copy session is terminated, the information is no longer available on the virtual device.

If a copy session has been restored, the restored session must be terminated first, before the original copy session is allowed to be terminated.

() NOTE:

If the state is RestInProg, then the -symforce option must be applied to terminate the session.

Terminating a duplicate snap session

You can terminate a duplicate snap session in the Created state using the symsnap terminate -duplicate command. For example, enter:

symsnap -g ProdDB terminate -duplicate VDEV001 vdev ld VDEV002

Once a duplicate snap session is activated, the session appears as normal snap session and is terminated using the **terminate** command without the -duplicate option.

Querying snap pairs

You can perform a query to determine the state of a snap pair or all snap pairs in a device group, composite group, or device file. The query is sent through the gatekeeper device to the array, returning with information about the state of the snap pair(s).

The following forms enable you to target devices in a device group, composite group, or device file:

```
symsnap -g DgName query
symsnap -cg CgName query
symsnap -f[ile] FileName query
```

Examples

To query the state of the snap pairs in the prod device group, enter:

symsnap -g prod query

You can also obtain results using the -offline option, which looks at your configuration based on the host database.

The results of the query include the following information for each member of a snap pair in a device group:

- Logical device name
- Device name
- Number of invalid tracks
- Snap pair state

Using the -summary option

If you use the -summary option with the **query** argument, the results of the query will include the following information:

- Number of snap pairs in each snap pair state
- Number of invalid tracks
- Synchronization rate
- Estimated time to completion

The synchronization rate and estimated time to completion are shown only when -i or -c is specified and their has been a change in the number of invalid tracks since the previous iteration.

The -summary option also works with the **verify** argument.

Example

To view the number of snap pairs in the prod device group that are in each state, and to view the estimated time to completion, enter:

```
symsnap -g prod query -summary -i 60
```

Verifying snap pair states

You can use the symsnap verify command to verify whether one or all snap pair(s) in a device group, composite group, or device file are in a particular state. The command can be used in scripts to guarantee that the snap device pair(s) are in a particular state prior to executing subsequent SYMCLI commands. If you do not specify any qualifiers with symsnap verify, the default is to check for the Copied state.

The following forms enable you to target devices in a device group, composite group, or device file:

```
symsnap -g DgName verify
symsnap -cg CgName verify
symsnap -f[ile] FileName verify
```

The following options qualify the symsnap verify command. If you need to verify a concurrent snap pair, include -concurrent with the option (for example, -copied -concurrent):

- -copied verifies that the copy sessions are in the Copied state.
- -copyonwrite verifies that the copy sessions are in the CopyOnWrite state.
- -created verifies that the copy sessions are in the Created state.
- -recreated verifies that the copy sessions are in the Recreated state.
- -restingrog verifies that the copy sessions are in the RestInProg state
- -restored verifies that the copy sessions are in the Restored state.

Examples

For a multi-snap or concurrent snap device group, specifying the snap on the command line ensures that the verify operation checks the status of the snap. Otherwise, the verify operation checks the status of the standard device, which may no longer be established with the snap that you want to verify. For example, the following command returns the status of standard device DEV001 with its last paired snap:

symsnap -g ProdBgrp verify DEV001

But the following command returns the status of a specific snap pair (DEV001 with DEV005):

symsnap -g ProdBgrp verify DEV001 sym ld DEV005

The following command checks status every 30 seconds until all snap pairs in the device group (ProdBgrp) or composite group (MyConGrp) are in the Copied state (the default when no state is specified on the command line):

```
symsnap -g ProdBgrp -i 30 verify
```

symsnap -cg MyConGrp -i 30 verify

Possible outputs at 30-second intervals can be that none, not all, or all devices are copied.

The verify action returns a value of zero (code symbol CLI_C_SUCCESS) if the verify criteria are met, or one of the unique codes in Using options to verify a snap pair state on page 69 if the verify criteria are not met.

Table 9. Using options to verify a snap pair state

| Options used with Verify | Code number | Code symbol |
|--------------------------|-------------|---------------------------|
| -copied | 55 | CLI_C_NOT_ALL_COPIED |
| -copied | 56 | CLI_C_NONE_COPIED |
| -copyonwrite | 66 | CLI_C_NOT_ALL_COPYONWRITE |
| -copyonwrite | 67 | CLI_C_NONE_COPYONWRITE |
| -created | 60 | CLI_C_NOT_ALL_CREATED |
| -created | 61 | CLI_C_NONE_CREATED |
| -recreated | 68 | CLI_C_NOT_ALL_RECREATED |
| -recreated | 69 | CLI_C_NONE_RECREATED |
| -restinprog | 29 | CLI_C_NOT_ALL_RESTINPROG |
| -restinprog | 30 | CLI_C_NONE_RESTINPROG |
| -restored | 12 | CLI_C_NOT_ALL_RESTORED |
| -restored | 13 | CLI_C_NONE_RESTORED |

Using a BCV as the snap source

As shown in Creating a virtual copy from a BCV on page 71, you can create a virtual copy session between a BCV source device and a virtual target device. The controlling host performs I/O to the standard device that is established with a BCV as part of a BCV pair. At some point, when the BCV is synchronized with the standard device, you can split the BCV from the standard and create a point-in-time copy of the BCV. The split operation must be entirely complete including the background phase before you can create a copy session on it.

TimeFinder/Mirror Operations on page 94 provides additional information on using the symmir command and how to perform an instant split operation.

Pair states ruling snap operations

Because other operations can conflict with your copy session, certain rules must be considered. The availability of some snap copy operations depends on the current SRDF state, clone state, and BCV pair state. The following rules apply to certain BCV pair states:

• If the source of a symsnap create or activate operation is a BCV, the BCV pair state must be Split. The Split must be totally complete before the operation is allowed.

(i) NOTE:

The existing BCV snap copy session must be terminated before the BCV can be reestablished or restored again with its standard device.

• A TimeFinder standard source device cannot be created, activated or restored in a copy session if the BCV pair state is SplitBfrRest or RestInProg.

(i) NOTE:

If you have an active snap copy session from a standard device that also has an established BCV and you attempt to restore the standard from the BCV, the restore operation may fail due to insufficient space on the SAVE device. In this case it may be best to first restore and terminate the snap copy session, then attempt the BCV restore operation.

• The symsnap terminate command is allowed for all BCV pair states.

For the TimeFinder pair states that rule TimeFinder/Snap copy sessions, refer to TimeFinder State Rules Reference on page 160.

For information regarding possible SRDF pair state conflicts, refer to State rules for TimeFinder/Snap operations on page 199.

For a description of each BCV pair state, refer to BCV pair states on page 146.

Example: Creating a virtual copy from a BCV

About this task

The following example creates a copy of source device BCV001 in device group ProdDB on an array to target device VDEV005 on the same array.

Once the copy session is activated, Host C can access the virtual target device tracks containing the device pointers to the point-in-time copy. If Host B writes to BCV device tracks, TimeFinder immediately copies the original tracks to the SAVE device before allowing new data to overwrite those BCV tracks.

() NOTE:

In this example, where multiple hosts have access to the BCV source, consider using the -not_ready option with the **split** command to make the BCV not ready. This enables you to keep the same data on the BCV and virtual devices.

If you decide to use this option, you may need to release any Not Ready state imposed on any devices after the session completes.

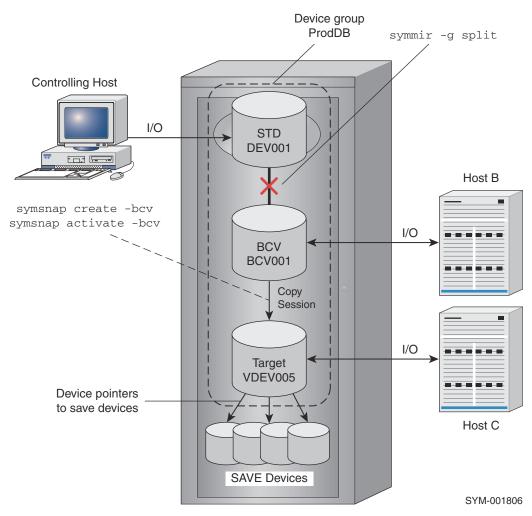

Figure 16. Creating a virtual copy from a BCV

For this example, the device pair was set in the Not Ready state. The following steps outline the example shown in Creating a virtual copy from a BCV on page 71:

Steps

1. Perform an instant split on the BCV pair. Use the -not_ready option to prevent the BCV's host from writing to it:

symmir -g ProdDB split DEV001 -not_ready -noprompt

2. Verify that the background split is complete. The following command checks every five seconds:

```
symmir -g ProdDB verify DEV001 -split -bg -i 30
```

3. Create a copy session between the BCV source device BCV001 and the virtual target device VDEV005:

```
symsnap -g ProdDB create BCV001 vdev ld VDEV005
```

or

```
symsnap -g ProdDb create -bcv
```

(i) NOTE:

Using the -bcv option applies the command within the device group to use BCV devices as the source and VDEV devices as the target.

4. Activate the copy session to Host C:

```
symsnap -g ProdDB activate BCV001 vdev ld VDEV005
```

or

```
symsnap -g ProdDb activate -bcv
```

5. Query the state of the copy operation and verify the CopyOnWrite state:

```
symsnap -g ProdDB query
```

symsnap -g ProdDB verify BCV001 -copyonwrite

6. When the application has finished accessing the data, the copy session and pair relationship can be terminated:

```
symsnap -g ProdDB terminate BCV001 vdev ld VDEV005 -noprompt
```

or

```
symsnap -g ProdDb terminate -bcv
```

7. Incrementally re-establish the BCV pair:

symmir -g ProdDB establish DEV001 -noprompt

Creating multiple virtual copies

This section describes how to create multiple virtual copies from a standard device and a BCV device.

Creating multiple virtual copies from a standard device

About this task

Creating multiple virtual copies from a standard device on page 73 illustrates creating copy sessions for multiple targets from a standard source device **DEV001** to four virtual target devices (**VDEV005**, **VDEV006**, **VDEV007** and **VDEV008**) with various hosts accessing them.

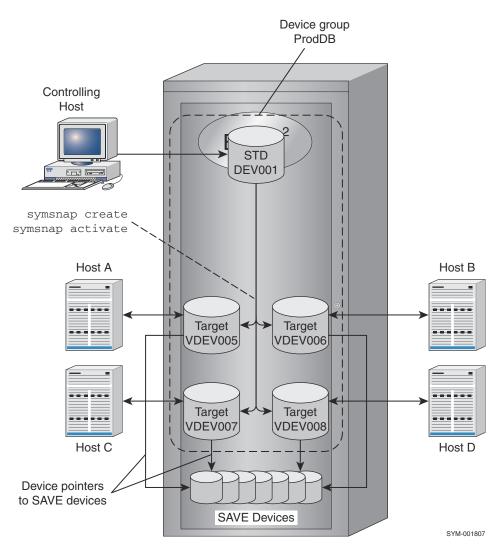

Figure 17. Creating multiple virtual copies from a standard device

() NOTE:

A separate copy session must be created between the source device (DEV001) and each target device (VDEV005, VDEV006, VDEV007, and VDEV008).

The following steps outline the example shown in Creating multiple virtual copies from a standard device on page 73:

Steps

1. Create a copy session between the standard source device **DEV001** and each of the four virtual target devices VDEV005, VDEV006, VDEV007, and VDEV008:

symsnap -g ProdDB create DEV001 vdev ld VDEV005 symsnap -g ProdDB create DEV001 vdev ld VDEV006 symsnap -g ProdDB create DEV001 vdev ld VDEV007 symsnap -g ProdDB create DEV001 vdev ld VDEV008

2. Activate the copy operation with one command to activate all sessions simultaneously:

| symsnap -g ProdDB activate | DEV001 vdev ld VDEV005 DEV001 vdev ld VDEV006 DEV001 vdev ld VDEV007 DEV001 vdev ld VDEV008 |
|----------------------------|--|
| | |

3. Using the **query** argument, you can display the state of all devices involved in the copy operation by including the -multi option:

symsnap -g ProdDB query -multi

4. When the host devices have finished using the copy sessions, the pair relationships can be terminated individually as needed:

symsnap -g ProdDB terminate DEV001 vdev 1d VDEV005 -noprompt symsnap -g ProdDB terminate DEV001 vdev 1d VDEV006 -noprompt symsnap -g ProdDB terminate DEV001 vdev 1d VDEV007 -noprompt symsnap -g ProdDB terminate DEV001 vdev 1d VDEV008 -noprompt

Creating multiple virtual copies from a BCV device

About this task

Creating multiple virtual copies from a BCV device on page 75 illustrates how to create multiple copy sessions from a BCV source device **BCV001** to four virtual target devices (VDEV005, VDEV006, VDEV007, and VDEV008) with various hosts accessing them.

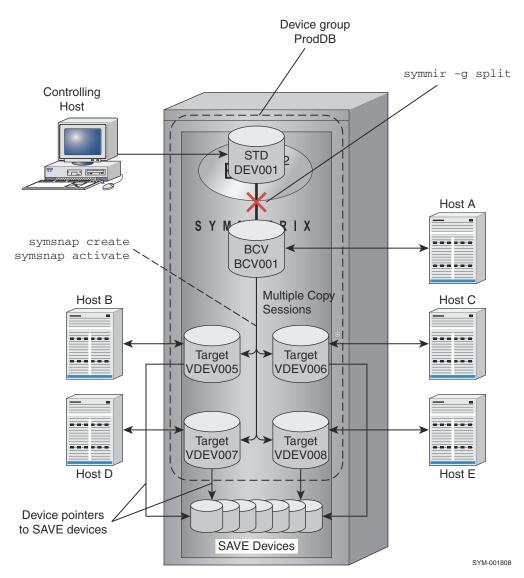

Figure 18. Creating multiple virtual copies from a BCV device

The following steps outline the example shown in Creating multiple virtual copies from a BCV device on page 75:

Steps

1. Perform an instant split on the BCV pair. Use the -not_ready option to prevent the BCV's host from writing to the device:

symmir -g ProdDB split DEV001 -not ready -noprompt

TimeFinder/Mirror Operations on page 94 provides additional information on using the symmir command and performing an instant split operation.

2. Verify that the background split is complete. The following command checks every five seconds:

symmir -g ProdDB verify DEV001 -split -bg -i 30

3. Create a copy session between the BCV source device BCV001 and each of the four virtual target devices VDEV005, VDEV006, VDEV007, and VDEV008:

```
symsnap -g ProdDB create BCV001 vdev ld VDEV005
symsnap -g ProdDB create BCV001 vdev ld VDEV006
symsnap -g ProdDB create BCV001 vdev ld VDEV007
symsnap -g ProdDB create BCV001 vdev ld VDEV008
```

4. Activate the copy operation with one command to activate all sessions simultaneously

| symsnap -g ProdDB activate | BCV001 vdev ld VDEV005 BCV001 vdev ld VDEV006 BCV001 vdev ld VDEV007 BCV001 vdev ld VDEV008 |
|----------------------------|--|
| | |

5. Using the **query** argument, you can display the state of all devices involved in the copy operation by including the -multi option:

symsnap -g ProdDB query -multi -BCV

6. When the host devices have finished accessing the data, the copy sessions and pair relationships can be terminated individually as needed:

symsnap -g ProdDB terminate BCV001 vdev ld VDEV005 -noprompt
symsnap -g ProdDB terminate BCV001 vdev ld VDEV006 -noprompt
symsnap -g ProdDB terminate BCV001 vdev ld VDEV007 -noprompt

7. Incrementally reestablish the BCV pair (DEV001 and BCV001):

symmir -g ProdDB establish DEV001 -noprompt

Attaching source and target virtual devices

Use the **symsnap attach** and **detach** commands to set up preferred device pairs. Pre-determining attached device pairs eliminates the need to specify copy session target devices from within the device group for the create and activate arguments. The attached pairs will be used whenever a **symsnap** operation is requested for the specified device group. If a symsnap create or activate command does not specify a device pair from within the device group, the attached pair will automatically be used for the operation.

() NOTE:

The **attach** option can only be used when attaching a standard source device with a target VDEV device. You cannot use symsnap attach if the source device is a BCV device.

To set up a preferred attached device pair between source device DEV001 in device group ProdDB and target device VDEV002, enter:

symsnap -g ProdDB attach DEV001 vdev ld VDEV002

To invoke a copy session operation from within a specified device group ProdDB using the pre-determined device pairs, enter:

```
symsnap -g ProdDB create
symsnap -g ProdDB activate
To detach (undo) the preferred device pair relationship, enter:
symsnap -g ProdDB detach DEV001 vdev 1d VDEV002
```

Using composite groups to manage snap pairs across arrays

About this task

Using a composite group when a set of devices spans two arrays on page 77 illustrates a production host that is locally connected to two arrays (A and B). A composite group is defined on the production host and includes source devices and target devices from these arrays. The target devices are virtual devices.

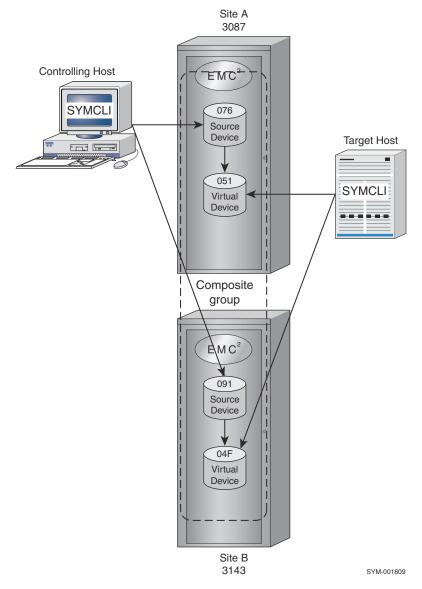

Figure 19. Using a composite group when a set of devices spans two arrays

Although snap operations might normally be performed from the production host because the composite group is defined there in its SYMAPI database, there are methods that would allow you to initiate copy sessions from another locally connected host like the target host. One way is to copy the composite group definition to another host.

A more efficient method is to enable Group Name Services (GNS), which automatically propagates the composite group definition to the arrays and other locally attached hosts that are running the GNS daemon.

The following steps outline the setup required for controlling a set of snap pairs that span two arrays, as shown in Using a composite group when a set of devices spans two arrays on page 77:

Steps

1. From the production host, create a Regular type composite group (for example, MyGrp):

symcg create MyGrp -type regular

2. Add to the composite group those standard devices on array A (3087) and array B (3143) that are the source devices:

```
symcg -cg MyGrp -sid 3087 add dev 0076
symcg -cg MyGrp -sid 3143 add dev 0091
```

3. Add a virtual device from each array to the composite group:

symcg -cg MyGrp -sid 3087 add dev 0051 -vdev symcg -cg MyGrp -sid 3143 add dev 004F -vdev

4. Create snap pair sessions from those devices in the composite group:

symsnap -cg MyGrp create

5. Activate the snap pair sessions:

symsnap -cg MyGrp activate

Composite group support allows the source of a snap operation to be a standard device (as shown in step 2 above) or a BCV device. If you add BCV devices to the composite group for the purpose of being snap sources, you must use the -bcv option with the symsnap commands. For example, the following command creates snap pairs in the composite group using the BCVs as source devices:

symsnap -cg MyGrp create -bcv

You can add nonsource BCV devices to the composite group for the purpose of restore operations. Composite group support allows you to restore to either the original source standard device or to a BCV that has been split from its paired standard device. The following commands split all BCV pairs in the composite group and perform a restore operation from the virtual devices to the BCVs:

symmir -cg MyGrp split

```
symsnap -cg MyGrp restore -bcv
```

For more information about performing an incremental restore to a BCV that is split from the original source device, refer to Incrementally restoring to a BCV on page 64.

You can control specific snap pairs within the composite group. To create and activate the DEV001 and VDEV002 snap pair from devices in the group:

```
symsnap -cg MyGrp create DEV001 vdev ld VDEV002
symsnap -cg MyGrp activate DEV001 vdev ld VDEV002
```

Snapping a copy on a remote array

About this task

You can use a device group or composite group to snap devices on a remote array as shown in Snapping a copy on a remote array on page 79. Performing SYMCLI commands from the controlling host allows the remote virtual device to receive a copy of the data from the R2 device. Remote Host A can access the snap data.

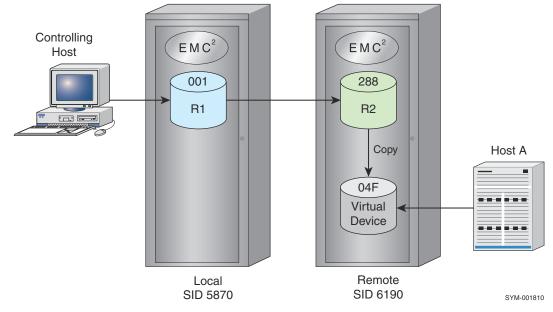

Figure 20. Snapping a copy on a remote array

The following steps outline an example of snapping local device data on a remote array:

Steps

1. Create an RDF1-type device group or composite group (for example, a device group named remotesnaps).

```
symdg create remotesnaps -type rdf1
```

2. Add to the device group an R1 standard device (001) to hold the production data. Add a virtual device (04F) on the remote to hold the snap copy:

symdg -g remotesnaps add dev 001 -sid 5870

symdg -g remotesnaps add dev 04F -rdf -vdev

If the local array has more than one RDF group (that is, concurrent RDF) linking the remote array, include the RDF group option (for example, -rdfg 2) when adding the remote virtual device.

3. Create a snap pair session from the devices in the device group:

symsnap -g remotesnaps create -rdf DEV001 vdev ld RVDEV001

4. Activate the snap pair session:

symsnap -g remotesnaps activate -rdf DEV001 vdev ld RVDEV001

5. To query the progress of the remote snap operation:

```
symsnap -g remotesnaps query -rdf
```

Snapping a copy from a remote BCV

Using SRDF technology and the TimeFinder **-rdf** option, you can snap a copy from a BCV located on a remote array (Snapping from a remote BCV source device on page 80). By doing this, the remotely associated BCV is synchronized with the R2 device until you decide to split the BCV pair and snap a copy from the BCV to the virtual device.

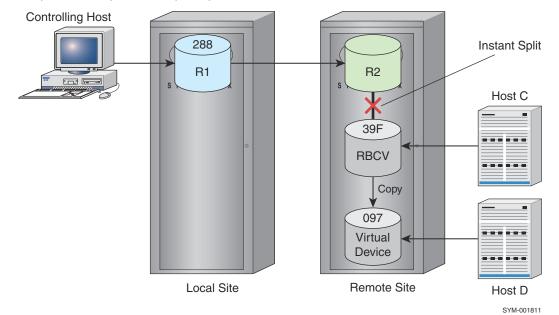

Figure 21. Snapping from a remote BCV source device

The following steps outline an example of creating a copy session between a remote BCV source device and a remote virtual device:

1. Create an RDF1-type device group or composite group (for example, a device group named Rdf1Grp):

symdg create Rdf1Grp -type rdf1

1. Add to the device group an R1 standard device on the local array to hold production data. Add a virtual device on the remote array to hold the snap copy:

symdg -g Rdf1Grp add dev 288

symdg -g Rdf1Grp add dev 097 -rdf -vdev

1. Associate with the device group an RBCV to be the snap source on the remote array:

symbov -g Rdf1Grp associate dev 39F -rdf

1. Establish standard device 288 (DEV001) with the RBCV:

```
symmir -g Rdf1Grp establish -full DEV001 -rdf
```

1. When the remote BCV pair is fully synchronized, perform an instant split on the BCV pair:

symmir -g RdflGrp split -rdf

1. When the background split is complete, create and activate a copy session between the remote BCV source device and the remote virtual device:

```
symsnap -g Rdf1Grp snap create -rbcv RBCV001 vdev ld RVDEV001
```

symsnap -g Rdf1Grp snap activate -rbcv RBCV001 vdev ld RVDEV001

1. To query the progress of the remote snap operation or verify the copy session, you can issue the following commands that examine the snapped pair (the RBCV source device and the virtual device):

```
symsnap -g RdflGrp query -rbcv
```

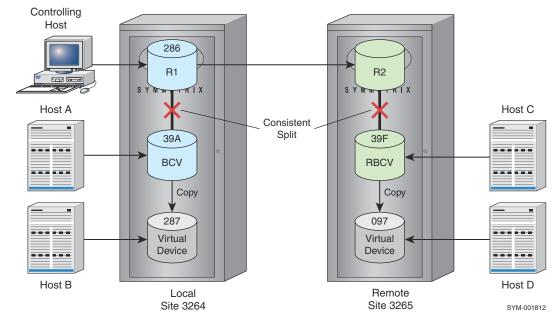

```
symsnap -g RdflGrp verify -rbcv
```

Snapping copies of a source device's data locally and remotely

About this task

Snapping copies on local and remote arrays on page 81 combines elements of Snapping a copy on a remote array on page 79 and Snapping a copy from a remote BCV on page 80 to illustrate how to snap copies of a source device's data to devices on two arrays. By splitting the BCV pairs on both sides at the same time with a consistent split operation, the BCVs on both sides contain data that is consistent with the R1 source data up to the time of the split.

The controlling host can then perform a local snap and a remote snap, resulting in the virtual devices on both sides having copies of the source device's data (provided that the BCVs were not written to by their hosts prior to the snap operation).

The following steps outline the example shown in Snapping copies on local and remote arrays on page 81:

Steps

1. Create an RDF1-type device group or composite group (for example, a device group named Rdf1Grp):

symdg create Rdf1Grp -type rdf1

2. Add to the device group an R1 standard device (286) on the local array (-sid 3264) to hold production data. Add local virtual device 287 and remote virtual device 097 to hold the snap copies:

symdg -g RdflGrp -sid 3264 add dev 286 symdg -g RdflGrp -sid 3264 add dev 287 -vdev symdg -g RdflGrp -sid 3264 add dev 097 -rdf -vdev

3. Associate with the device group local BCV 39A and remote BCV 39F:

```
symbov -g RdflGrp -sid 3264 associate dev 39A
```

symbov -g Rdf1Grp -sid 3264 associate dev 39F -rdf

4. Establish the BCV pairs on both arrays. DEV001 is the logical device name of the R1 source device (286):

symmir -g Rdf1Grp establish -full DEV001

symmir -g Rdf1Grp establish -full DEV001 -rdf

5. When the BCV pairs are fully synchronized, perform a consistent split on both BCV pairs. You can perform this operation with one command, using the -both_sides option. For example:

symmir -g RdflGrp split -consistent -both sides

(i) NOTE:

To use the -consistent and -both_sides options, the SRDF pairs must be synchronized and in SRDF mode SYNCHRONOUS.

6. When the background split is complete, create the local and remote snap pairs:

symsnap -g Rdf1Grp create -bcv BCV001 vdev ld VDEV001

symsnap -g Rdf1Grp create -rbcv RBCV002 vdev ld RVDEV002

7. Activate the copy sessions for the local and remote snap pairs:

symsnap -g Rdf1Grp activate -bcv BCV001 vdev ld VDEV001

symsnap -g Rdf1Grp activate -rbcv RBCV002 vdev ld RVDEV002

8. To query the progress of the local snap operation or verify when the local copy is complete, you can issue the following commands that examine the local snap pair:

symsnap -g Rdf1Grp query -bcv

symsnap -g Rdf1Grp verify -bcv

9. To query the progress of the remote snap operation or verify when the remote copy is complete, you can issue the following commands that examine the remote snap pair:

symsnap -g RdflGrp query -rbcv symsnap -g RdflGrp verify -rbcv **10.** When subsequent snaps are no longer required, you can terminate the copy sessions by issuing commands that end copy sessions for the local and remote snap pairs:

```
symsnap -g RdflGrp terminate -bcv BCV001 vdev ld VDEV001 -bcv
symsnap -g RdflGrp terminate -rbcv RBCV002 vdev ld RVDEV002
```

Snapping multiple copies

This configuration snaps from a BCV source to four virtual devices on each array instead of to one virtual device on each array. This illustrates how a single **symsnap** command can create an image of a source device (a BCV in this case) on four virtual devices simultaneously.

As mentioned previously, by splitting the BCV pairs on both sides of an SRDF configuration at the same time, the BCVs on both sides contain data that is consistent with the R1 source data up to the time of the split. The controlling host can then perform a local snap and a remote snap, resulting in virtual devices on both sides having copies of the source device's data (provided that the BCVs were not written to by their hosts prior to the snap operation). In this configuration, 10 hosts can have access to copies of the source device's data (two copies on BCVs, and eight copies on virtual devices).

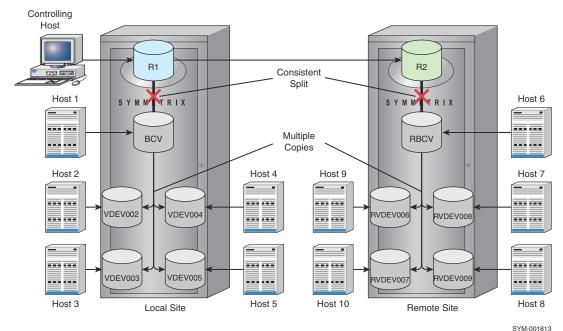

Figure 23. Snapping multiple copies on local and remote arrays

The process for building an RDF1-type device group is similar to the previous section. The difference is that a device group for this configuration contains the R1 standard device, two BCVs, and eight virtual devices. Establishing and splitting both BCV pairs is the same as the previous section.

What is different about this configuration is the ability to snap copies from a single source to multiple virtual devices simultaneously with a single command. Before initiating the snap operation, however, you must wait for completion of the BCV-pair background split involving the BCV that will be the source for the snap.

To snap copies to the four local virtual devices (DEV002, DEV003, DEV004, and DEV005) from the local BCV source device (BCV001), issue the symsnap create and the symsnap activate commands:

```
symsnap -g RdflGrp create -bcv BCV001 vdev ld VDEV002
symsnap -g RdflGrp create -bcv BCV001 vdev ld VDEV003
symsnap -g RdflGrp create -bcv BCV001 vdev ld VDEV004
```

symsnap -g RdflGrp create -bcv BCV001 vdev ld VDEV005

| symsnap -g RdflGrp activate -bcv | BCV001 vdev ld VDEV002 |
|----------------------------------|------------------------|
| | |
| | BCV001 vdev ld VDEV003 |
| | |
| | BCV001 vdev ld VDEV004 |
| | |
| | BCV001 vdev ld VDEV005 |
| | |

To snap copies to the four remote virtual devices (DEV006, DEV007, DEV008, and DEV009) from the remotely associated BCV source device (BCV002), issue the **symsnap** commands with the -rbcv option:

symsnap -g Rdf1Grp create -rbcv RBCV002 vdev ld RVDEV006 symsnap -g Rdf1Grp create -rbcv RBCV002 vdev ld RVDEV007 symsnap -g Rdf1Grp create -rbcv BCV002 vdev ld RVDEV008 symsnap -g Rdf1Grp create -rbcv BCV002 vdev ld RVDEV009

Snapping a copy at the tertiary site of a cascaded SRDF configuration

About this task

Using SRDF technology and the TimeFinder-hop2 option, you can snap devices on an array located at the tertiary site of a cascaded SRDF configuration (Snapping a copy at the tertiary site of a cascaded SRDF configuration on page 85). Performing SYMCLI commands from the controlling host allows the remote virtual device to receive a copy of the data from the R1 device. Remote Host A can access the snap data.

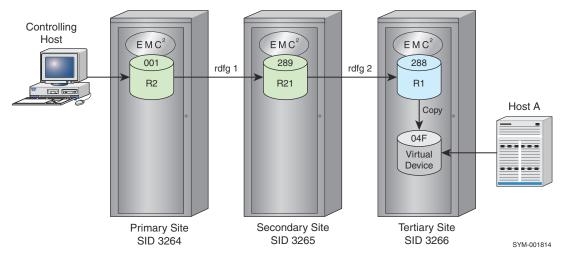

Figure 24. Snapping a copy at the tertiary site of a cascaded SRDF configuration

The following steps outline an example of snapping local device data on an array located at the tertiary site of a cascaded SRDF configuration:

Steps

1. Create an RDF2-type device group or composite group (for example, a group named remotesnaps):

To create an RDF2-type device group:

symdg create remotesnaps -type rdf2

To create an RDF2-type composite group:

symcg create remotesnaps -type rdf2

2. Add devices to the group. From the array at the primary site, add an R2 standard device. From the array at the tertiary site, add a virtual device to hold the snap copy.

To add devices to a device group:

symdg -g remotesnaps -sid 3264 add dev 001

symdg -g remotesnaps -hop2 -rdfg 1 -remote rdfg 3 -vdev add dev 04f

To add devices to a composite group:

symcg -cg remotesnaps -sid 3264 add dev 001

symcg -cg remotesnaps -sid 3264 -hop2 -rdfg 1 -remote rdfg 3 -vdev add dev 04f

3. Create a snap pair session from the devices in the group:

symsnap -g remotesnaps -exact -hop2 create

4. Activate the snap pair session:

symsnap -g remotesnaps -hop2 activate

5. To query the progress of the remote snap session:

```
symsnap -g remotesnaps query -hop2
```

6. To terminate the remote snap session:

```
symsnap -g remotesnaps -hop2 terminate
```

Snapping a copy from a clone target device

You can perform snap operations from clone target devices. This feature allows the target device of a clone session to be used as a source device for one or more snap sessions.

The following restrictions apply to snap from clone target devices:

- The original clone session (symclone) must be in the Copied or Split state.
- After one or more snap sessions begin using the original clone devices, the only action permitted on the original clone session is **terminate**. All other actions are blocked until all of the snaps are terminated.

The only actions permitted on a snap session with a clone session target as their source are activate and terminate. All other actions are blocked until the original clone session is terminated.

For example:

symclone -g DgName create symclone -g DgName activate symsnap -g DgName -bcv create symsnap -g DgName -bcv activate symsnap -g DgName -bcv terminate symclone -g DgName recreate

Command options with device groups or composite groups

Options to the **symsnap** -g and -cg command line arguments provide more action flexibility to control copy sessions when you are operating on device(s) of a specified device group or composite group. symsnap -g and -cg control arguments and possible options on page 86 lists the **symsnap** control operations and the possible options to use when targeting a specified device group or composite group or composite group.

| Options | Argument action | | | | | | | | | | |
|---------------------|-----------------|----------|---------------|----------|---------------|---------|-------|--------|--------|--------|--|
| | create | activate | duplicat e | recreate | terminat e | restore | query | verify | attach | detach | |

a. The -preservetgtlocks and -lockid option is not supported for -cg commands.

() NOTE:

For command syntax and descriptions of the symsnap options, refer to the EMC Solutions Enabler CLI Command Reference.

Command options with device files

With the **symsnap**-file command, you can perform snap control operations on device pairs defined in a device file. The device file includes a source device number, a target virtual device number, and the Symmetrix ID. symsnap -file control arguments and possible options on page 88 lists the **symsnap** control operations and the possible options to use when targeting device pairs specified in a device file.

| Options | Argumen | Argument action | | | | | | | | |
|---------------------|---------|-----------------|---------------|----------|---------------|---------|-------|--------|--------|--------|
| | create | activate | duplicat e | recreate | terminat e | restore | query | verify | attach | detach |

TimeFinder VP Snap Operations

This chapter describes how to perform TimeFinder VP Snap operations.

Topics:

- TimeFinder VP Snap overview
- Creating a VP Snap copy session
- Activating a VP Snap session
- Restoring a VP Snap session
- Terminating a VP Snap copy session

TimeFinder VP Snap overview

For a high-level overview of TimeFinder VP Snap functionality, refer to the EMC VMAX Family Product Guide.

VP Snap leverages TimeFinder/Clone technology to create space-efficient snaps for thin devices by allowing multiple sessions to share capacity allocations within a thin pool. VP Snap provides the efficiency of Snap technology with improved cache utilization and simplified pool management. With VP Snap, tracks can be stored in the same thin pool as the source, or in another pool of your choice.

VP Snap sessions copy data from the source device to the target device only if triggered by a host I/O. Read I/Os to protected tracks on the target device do not result in data being copied.

The figure below shows several VP Snap sessions sharing allocations within a thin pool

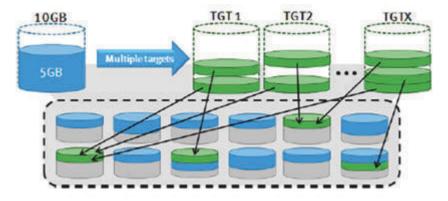

Figure 25. VP Snap sessions sharing allocations within a thin pool

Creating a VP Snap copy session

Example

To begin a VP Snap session and define DEV001 as the source device and DEV005 as the target device, enter:

symclone -g ProdDB create DEV001 sym ld DEV005 -vse

The following restrictions apply to VP Snap:

- • The -vse attribute may only be applied during the creation of the session.
- Both the source device and the target device must be thin devices.

- All of the VP Snap target devices for a particular source device must be bound to the same thin pool.
- $\circ~$ A rebind operation is not allowed for devices that are the target of a VP Snap session.
- Once created, VP Snap sessions cannot be changed to any other mode.
- \circ $\;$ The source device and the target device must be the same size.
- VP Snap sessions cannot be combined with TimeFinder/Clone nocopy sessions on the same source device.
- If a FAST VP target extent is part of a VP Snap session, the shared tracks cannot be moved between tiers.
- TimeFinder/Snap sessions and VP Snap sessions cannot coexist on a source device.

Activating a VP Snap session

Example

To activate the VP Snap session created in Creating a VP Snap copy session on page 91, enter:

symclone -g ProdDB activate DEV001 sym ld DEV005

This activates the copy operation from the source device to the target device. Activating the copy session places the target device in the Read/Write state. The target host can access the copied data and has access to data on the source host until the copy session is terminated.

() NOTE:

Copied data is made available as a point-in-time copy at the time of activation and not at the time that the session was created.

Using the establish command

To create and then immediately activate a copy session with a single command, you can use the **symclone establish** command.

Example

To create and then activate the copy session shown in the example in Creating a VP Snap copy session on page 91, enter:

symclone -g ProdDB establish DEV001 sym ld DEV005 -full -vse

() NOTE:

The **symclone establish** command sets the target device to Not Ready for a short time. If you are using a filesystem, unmount the target host before performing the establish command.

Restoring a VP Snap session

VP Snap supports incremental restore operations back to the original source device. Unlike TimeFinder/Clone restore operations, the source device does not have to be fully copied and the original session between the source device and the target device is maintained. The following restrictions apply:

- Only one restore session is allowed for the source device.
 - Because the original session is maintained, a VP Snap restore operation uses two session slots on the source device (one for the original session and one for the restore session).
 - If you have concurrent sessions off of a source device, all of the concurrent sessions must be in the Copied or CopyOnWrite state.
 - Splitting a clone device pair is not supported for VP Snap restored sessions.
 - Starting from the time of the initiation of the incremental restore command until the restore copy is complete, the following restrictions apply:
 - None of the existing sessions may be changed from one mode to another.

- None of the existing sessions may perform a differential recreate or incremental establish operation.
- No new sessions may be created with another create or full establish command.
 - In the case of an incremental restore, the original session copy direction is reversed and changed data is copied from the target device to the source device.

Example

To incrementally restore data from the target device (**DEV005**) created in the example Creating a VP Snap copy session on page 91to the original source device (DEV001), enter:

symclone -g ProdDB restore DEV001 sym ld DEV005

() NOTE:

When constructing a **symclone restore** command, the device receiving the data always appears first in the command, followed by the device from which the data is being copied. Therefore, in the above command, **DEV001** is actually the target of the data being copied from **DEV005**

Terminating a VP Snap copy session

Terminating a copy session deletes the pairing information in the array and removes any hold on the target device.

VP Snap restore operations maintain the original session, so when a VP Snap session is restored, both the original CopyOnWrite session and the restore session exist. In this case, the restored session must be terminated before the original session. This is done by specifying the **-restored** switch on the terminate command. Once the restored session is terminated, the original session may be terminated with a normal terminate command without the **-restored** switch.

Example

To terminate the restore session in the example in Restoring a VP Snap session on page 92 using the symclone command, enter:

symclone -g ProdDB terminate DEV001 sym ld DEV005 -restored

Example

To terminate the original session in the example in Creating a VP Snap copy session on page 91 using the symclone command, enter:

```
symclone -g ProdDB terminate DEV001 sym ld DEV005
```

TimeFinder/Mirror Operations

This chapter describes the business continuance model and explains how to manage and control TimeFinder/Mirror (BCV) devices.

() NOTE:

For configurations running Enginuity 5876, TimeFinder/Mirror functions are performed through TimeFinder/Clone software using a process called Clone Emulation. Clone Emulation mode makes the use of RAID-protected BCVs transparent to the TimeFinder/Mirror user.

Topics:

- Clone Emulation mode and TimeFinder/Mirror
- TimeFinder operations overview
- Listing BCV devices
- Associating BCV devices with a device group
- Disassociating BCV devices from a device group
- Moving BCV devices from one device group to another device group
- Managing BCV devices with composite groups
- Establishing BCV pairs
- Incrementally establishing BCV pairs
- Splitting BCV pairs
- Fully restoring BCV pairs
- Incrementally restoring BCV pairs
- Protecting BCV data during full or incremental restores
- Cancelling BCV pairs
- Querying BCV pairs
- Verifying BCV pair states
- Using composite groups to manage BCV pairs across arrays
- Preferred attachment of BCVs (optional operations)
- BCV pair states
- Command options with device groups
- Command options with composite groups
- Command options with device files
- Various remote multihop configurations

Clone Emulation mode and TimeFinder/Mirror

Clone Emulation mode is a mapping procedure that allows you to use RAID-protected BCV devices in a way that is transparent to TimeFinder/Mirror users. In Clone Emulation mode, Solutions Enabler CLI functions convert TimeFinder/Mirror commands to TimeFinder/Clone commands.

() NOTE:

For environments using Enginuity 5876, TimeFinder/Mirror uses Clone Emulation mode for all operations.

TimeFinder/Clone Emulation on page 96 contains greater detail.

() NOTE:

Data Domain devices are not supported as TimeFinder/Mirror source or target devices.

TimeFinder/Mirror

TimeFinder/Mirror is essentially a business continuance solution that allows the use of special *business continuance volume* (BCV) devices. Copies of data from a standard device (which are online for regular I/O operations from the host) are sent and stored on BCV devices to mirror the primary data. Uses for the BCV copies can include backup, restore, decision support, and applications testing. Each BCV device has its own host address, and is configured as a stand-alone device.

TimeFinder/Mirror involves associating and establishing the BCV device as a mirror of a specific standard device. As a result, the BCV device becomes inaccessible (*Not Ready* in Establishing a BCV pair on page 95) using its original device address while it is in an established pair. Once the BCV device is synchronized with its source, you can separate (*split*) it from the standard device with which it is paired, thereby making it available again to its host for backup or other host processes through its original device address.

After host processing on the BCV device is complete, the BCV may again be mirrored to a standard device (either the same device with which it was previously paired, or with a different device).

() NOTE:

Unless noted otherwise, all references to arrays discussed in the context of TimeFinder/Mirror indicate a DMX running Enginuity 5773 and lower.

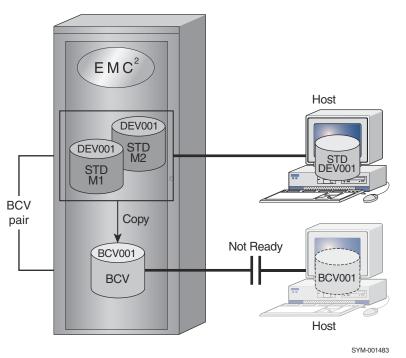

Figure 26. Establishing a BCV pair

A DMX array allows up to four mirrors for each logical volume. The mirror positions are commonly designated M1, M2, M3, and M4. A single BCV can be the second, third, or fourth mirror of the standard device. In Establishing a BCV pair on page 95, because standard device DEV001 is configured with two mirrors, BCV001 functions as the third mirror. A host logically views the M1/M2 mirrored devices as a single device.

SRDF-connected sites

SRDF is a Business Continuance solution that maintains a mirror image of data at the device level in arrays located in physically separate sites. In an SRDF configuration, the individual devices are designated as either a *source* or *target* to synchronize and coordinate SRDF activity.

Remotely mirroring the local standard

There are multiple types of SRDF-connected BCV devices. An SRDF-connected BCV can be paired with the R1 mirror or R2 mirror of the local RDF standard devices (RBCV) as shown in SRDF: Mirroring the local standard on page 96.

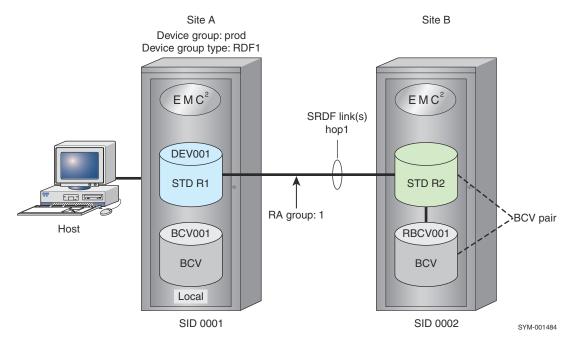

Figure 27. SRDF: Mirroring the local standard

Mirror types

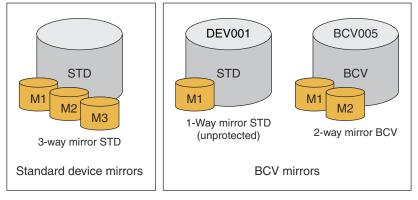

Once a BCV device is established as a mirror of a standard device, those two devices together are referred to as a *BCV pair*. The pair consists of two types of mirrors: the standard device mirror(s) and the BCV mirror.

The standard device mirrors contain copies of the data contained in their associated standard devices. There can be up to three standard device mirrors (M1, M2, M3).

A BCV mirror is a standard device mirror. It can be a two-way mirror (M1, M2) that is assigned upon creation of the BCV pair.

(i) NOTE:

Mirroring tasks such as establish, split, and restore use the symmir command and are described later in this chapter.

SYM-001489

Figure 28. Mirror configuration types

TimeFinder/Clone Emulation

TimeFinder automatically maps a TimeFinder/Mirror command to the executable of the appropriate TimeFinder/Clone command when it encounters a BCV that is a RAID 5 or RAID 6 protected device. Under Clone Emulation mode, TimeFinder/Clone initiates the pre-copying of data.

() NOTE:

While Clone Emulation mode is primarily a RAID 5 BCV implementation, it can also be used with any other BCV protection. Clone Emulation is available with the TimeFinder/Clone license and can be used with existing TimeFinder/Mirror scripts.

When you establish a BCV pair under Clone Emulation, the symmir establish -full command maps to the symclone create -precopy -differential command. This action causes copying to begin while still checking for new writes. The symmir split command maps to the symclone activate command. This action causes the data to become available to the host as an instant point-in-time copy.

TimeFinder commands mapped to clone operation on page 97 details the mapping of TimeFinder/Mirror operations to their TimeFinder/Clone operational equivalents.

| Table 12. TimeFinder commands mapped to clone operation |
|---|
|---|

| TimeFinder /Mirror symmir operations | TimeFinder/Clone symclone operations |
|--------------------------------------|---------------------------------------|
| FULL ESTABLISH | CREATE with pre-copy and differential |
| SPLIT | ACTIVATE or SPLIT |
| INCREMENTAL ESTABLISH | RECREATE |
| FULL RESTORE | FULL RESTORE |
| INCREMENTAL RESTORE | INCREMENTAL RESTORE |
| VERIFY | VERIFY |
| АТТАСН | АТТАСН |
| DETACH | DETACH |
| CANCEL | TERMINATE |
| PROTECT RESTORE | Default feature |
| PROT BCV ESTAB | Default feature ^a |
| QUERY | QUERY |
| List | List |

a. Only after the completion of split is the target device fully synchronized as in a protected BCV Establish.

To operate in a mixed BCV set of RAID 5 BCVs and non-RAID 5 BCVs, you must set the Clone Emulation environment variable to ENABLED:

SYMCLI CLONE EMULATION=ENABLED

In a mixed BCV set, if Clone Emulation is disabled (the default), any control operation produces an error when a RAID 5 BCV is encountered.

When in Clone Emulation mode, a standard device can be paired with as many as eight concurrent BCVs (RAID 5 or any other BCV protection). Issue the **symmir establish** -concurrent command for the same standard device up to eight times, adding one additional BCV each time.

The following limitations apply to TimeFinder/Clone Emulation:

- The TimeFinder reverse split feature is not allowed.
- Restores will always be protected restores.
- Incremental Restore (Reverse Re-Snap) will only be accepted if all tracks were originally copied from the source prior to the restore taking place.

() NOTE:

With Clone Emulation mode, an incremental restore will only be accepted if the devices are in a Split state and there is no active split.

The following option file settings will be ignored:

```
SYMAPI_DEFAULT_BCV_SPLIT_TYPE, SYMAPI_DEFAULT_BCV_RESTORE_TYPE
SYMAPI_DEFAULT_BCV_ESTABLISH_TYPE
```

- The maximum number of BCVs that can be incrementally established with a standard device will be eight instead of the 16 allowed by TimeFinder. SYMCLI MAX BCV PAIRS can at most be eight.
- The BCV states Split-Before-Sync and Split-Before-Restore are not valid states for an emulation device. In both cases, a forced split will complete the synchronization operation.

TimeFinder operations overview

These management operations can safely be performed with SYMCLI on a copy of an actively changing set of the business data. Business Continuance management operations include backing up a static copy of a database, or preparing for application upgrades.

Device external locks

SYMCLI/SYMAPI uses *device external locks* in the array to lock device pairs during SRDF and TimeFinder control operations. The *EMC Solutions Enabler Array Management CLI User Guide* provides more information on external locks.

Skip locks

During TimeFinder/Mirror operations, you can choose to bypass the device external locks on standard devices by using the -skip option with the symmir establish and split commands. If the specified source devices are either all locked or all unlocked, this option will explicitly not lock those source devices.

Preserve target locks

Device external locks are used to lock BCV device pairs and devices participating in a copy session during TimeFinder BCV, Snap, and Clone operations. For target devices that have been previously locked with the same lock holder ID, you can preserve the original lock for use in performing additional TimeFinder control operations.

Use the

```
-preservetgtlocks-lockid
```

options with the symmir establish, restore, and split commands to preserve the original device lock on target devices. You must specify the original lock holder ID number. This option causes the operation to not take out additional locks for the specified target devices.

Disallow synchronization actions

For some sites, it may be desirable to block users on a specific host from performing either an establish or restore operation on any of the devices. The SYMAPI_SYNC_DIRECTION parameter in the options file allows you to confine TimeFinder and SRDF operations to either just establish or restore actions. In this way, you can block a user on a host from executing a restore or an establish action using the following form:

```
SYMAPI_SYNC_DIRECTION=ESTABLISH | RESTORE | BOTH
```

where:

ESTABLISH confines the possible operations to just establish actions.

RESTORE confines the possible operations to just restore actions, which includes (allows) restore, failback, and R1 update actions.

BOTH (default) does not restrict any TimeFinder or SRDF actions.

() NOTE:

The EMC Solutions Enabler CLI Command Reference provides more details about the options file.

Wait for synchronization actions to complete

By default, the **symmir establish** command initiates a series of tasks that begins the synchronization of one or more BCV pairs. SYMCLI returns control to the caller while the establish operation is still in progress. The WAIT_FOR_BCV_SYNC parameter in the options file enables you to delay returning control to the caller until the establish operation (or a restore operation) is complete:

SYMAPI WAIT FOR BCV SYNC = TRUE | FALSE

where:

 $\ensuremath{\mathbb{TRUE}}$ waits for the operation to complete before returning control to the caller.

FALSE (default) returns control to the caller before the operation completes.

(i) NOTE:

The EMC Solutions Enabler CLI Command Reference provides more details about the options file.

Listing BCV devices

Configuration and status information is stored in the configuration database file for each device on every array, including BCV devices.

You can find all BCV devices on an array and view their physical and device names. In addition, you can display details about the BCV devices, including the BCV device name, the device name of the paired standard device, the number of invalid tracks for both the BCV device and the standard device, and the BCV pair state.

Examples

To list all the BCV devices that are visible to the host, enter:

symbov list pd

To list all the BCV devices, regardless of whether they are visible to the host, enter:

symbov list dev

To list all the BCV devices that have SCSI reservations, regardless of whether they are visible to the host, enter:

symbov -resv list

To list all the BCV sessions created on an array, enter:

symmir -sid SymmID list

To list all the BCV sessions created on array 3264:

symmir list -sid 3264

| Symmetrix ID: 00000003264 | | | | | | | | |

Associating BCV devices with a device group

Various compound (even multihop) remote configurations can be managed by your host using various SYMCLI control components. To perform operations on a BCV device using the SYMCLI, the BCV device must be associated with an existing device group or composite group (this is not a requirement when using a device file).

() NOTE:

For information on associating BCV devices with a composite group, refer to Associating BCV devices with a composite group on page 106.

When you associate a BCV device with a device group, you can assign it a logical device name. If you do not assign the BCV device a logical device name, a logical device name will be assigned automatically.

() NOTE:

Mirroring tasks such as establish, split, and restore use the symmir command and are described later in this chapter.

Examples

You can associate BCV devices with a device group by using either the physical device name, or the device name. To associate a BCV device with a physical device name of /dev/dsk/c0t2d0s2, to a device group named **prod**, and naming the BCV device **BCV7**, enter:

symbov -g prod associate pd c0t2d0 BCV7

To associate a BCV device, with a device name of 001F, to a device group named prod, naming the BCV device BCV5, enter:

symbov -g prod associate dev 001F BCV5

Moving device groups

By default, a BCV device cannot be associated with more than one device group at the same time when you are using one SYMCLI configuration database file. However, you can change this default behavior by enabling the SYMAPI_ALLOW_DEV_IN_MULT_GRPS parameter in the **options** file.

You can associate all BCV devices with a device group. Only BCV devices that are not already associated with a device group will be associated.

You can either associate all BCV devices that are visible to your host within a device group (the default), or are configured in an array.

To associate all BCV devices on array 123 with a device group prod, enter:

symbov -g prod -sid 123 associateall dev

Host-visible BCV devices

To associate all BCV devices visible to your host with the device group **prod**, enter:

symbcv -g prod associateall

You can also associate a range of BCV devices that are visible to your host. For example, to associate devices 039A through 039F with the device group **prod**, enter:

symbcv -g prod associateall -devs 039A:039F

You can associate remote BCV devices with a device group. The following options allow all remote BCV devices of a specific type to be associated with a device group:

-rdf specifies remote attached BCVs (RBCVs).

- -bcv specifies remote BCVs that mirror local BCVs (BRBCVs). This option must be used with the -rdf option.
- -rrdf specifies BCVs that are remotely associated with remote BCVs (RRBCVs).
- -hop2 specifies BCV devices (2BCVs) that are remotely associated on the second hop of a cascaded SRDF configuration.

SRDF-connected BCV device

An SRDF-connected BCV device must be associated with a device group before it can be paired with a remote standard device. Compounded remote configuration example on page 103 shows a device group of type RDF1 (there are three other device group types, RDF2, RDF21, and REGULAR, which are not shown).

If the group is an RDF1 type, then the remote BCVs (RBCV) can only be paired with the R2 mirrors on the remote array. If the group is an RDF2 type, then the remote BCVs can only be paired with the R1 mirrors on the remote array. When dealing with concurrent RDF devices, you can only remotely associate with one RDF group.

To associate an SRDF-connected BCV device to a device group named prod, and assign it a logical device name of RBCV001, enter:

symbor -sid 123 -g prod -rdf -RDFG 1 associate dev 000B

where:

123 is the ID of the local array.

-rdf specifies a remote attachment.

-RDFG 1 specifies the RDF group number (or RA group number) 1 at the local array through which the remote BCV is reached.

dev 000B specifies the device name of the BCV on the remote array.

In this example, the remote BCV pair is mirroring the local standard device as shown in Compounded remote configuration example on page 103.

SRDF-connected BCV mirror device

You can also associate a remote BCV pair that mirrors a local BCV device as shown in Compounded remote configuration example on page 103. For example:

symbor -sid 123 -g prod -rdf -bor -RDFG 2 associate dev 002A

where:

123 is the ID of the local array.

-rdf specifies a remote attachment.

-bcv specifies that it is a remote BCV that mirrors the local BCV.

-RDFG 2 specifies an RDF group number 2, through which the remote BCV is reached.

Compounded remote configuration

Compounded remote configuration example on page 103 shows how devices in a compounded remote configuration can be associated.

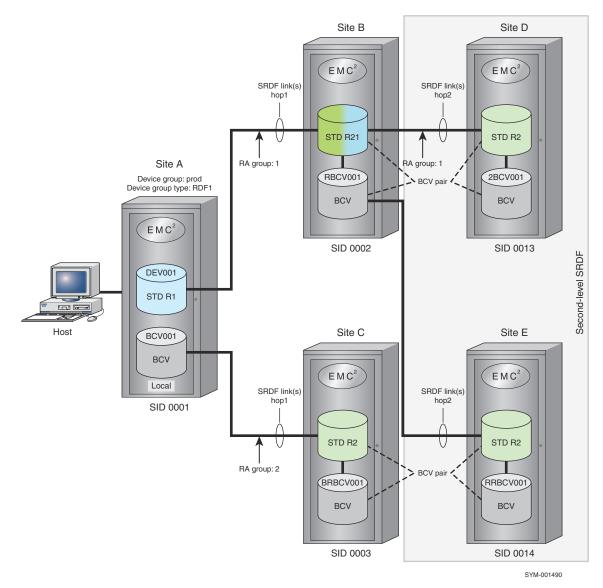

Figure 29. Compounded remote configuration example

- At site A, the SRDF links remotely mirror a local array.
- The remote site B functions as the remote mirror to the standard devices at site A.
- Remote site C (third site) uses an SRDF link to remotely mirror the BCV devices in the array at site A.
- The second-level SRDF shows how:
 - SRDF can be cascaded where remote site D (the Tertiary site) functions as a remote partner of the R21 device, which is the remote partner of the local RDF standard device.
 - SRDF can include multiple sites, for example where remote site E functions as a remote mirror to the standard devices of site A.

Disassociating BCV devices from a device group

Once a BCV device has been associated with a device group, you can disassociate it when the BCV device is in a state that allows it to be disassociated.

You can disassociate a BCV device by using either the physical device name, the device name, or the logical device name.

To disassociate a BCV device named **BCV7** from the **prod** device group, enter:

symbov -g prod disassociate ld BCV7

To disassociate a BCV device on device **000F** from the **prod** device group, enter:

symbcv -g prod disassociate dev 000F

If the BCV device that you want to disassociate from a device group is currently paired via TimeFinder, TimeFinder/Snap, or TimeFinder/Clone, the -force option must be used.

(i) NOTE:

When you use the **-force** option, SYMCLI does not access the array (an offline operation). It disassociates the device from the device group without access to the array.

SRDF-connected BCV pair

An SRDF-connected BCV device can be disassociated from a device group.

You can disassociate a BCV device using either the device name or the logical device name.

To disassociate a remote BCV device that has a logical device name of RBCV001 from a device group named SAMPLE1, enter:

symbov -g SAMPLE1 -rdf disassociate ld RBCV001

To disassociate a remote BCV device that has a device name of 002B from a device group named SAMPLE1, enter:

symbov -g SAMPLE1 -rdf disassociate dev 002B

If you are attempting to disassociate a remote BCV device from a device group, and the BCV device is in the synchronized, restored, or transient BCV state, you must use the -force option.

() NOTE:

When you use the -force option, SYMCLI does not access the array (an offline operation). It disassociates the device from the device group without access to the array.

Remote SRDF-connected BCV pair

You can disassociate a remote BCV pair that mirrors the local BCV device, which is shown associated in Compounded remote configuration example on page 103.

For example:

symbor -sid 123 -q SAMPLE1 -rdf -bor disassociate dev 002A

where:

-rdf specifies a remote attachment.

-bcv specifies that it is a remote BCV that mirrors the local BCV.

Remote BCV or a remote BCV pair

You can disassociate a remote BCV that mirrors the remote BCV device, which is shown associated in Compounded remote configuration example on page 103. This option can be used to disassociate a BCV device that is accessible via SRDF links two hops away. The group must be an RDF group.

For example:

symbov -sid 123 -g SAMPLE1 -rrdf disassociate dev 002A

where:

-rrdf specifies the BCV is being remotely disassociated with a remote BCV in the group.

Remote BCV on the second hop of a cascaded SRDF configuration

You can disassociate a remote BCV on the second hop of a cascaded SRDF configuration, which is shown associated in Compounded remote configuration example on page 103. This option can be used to disassociate a BCV device that is accessible via SRDF links two hops away. The group must be an RDF group.

For example:

symbor -sid 123 -g SAMPLE1 -hop2 disassociate dev 002A

where:

-hop2 specifies the BCV is in the second hop of a cascaded SRDF.

Moving BCV devices from one device group to another device group

The symbol command can be used to move one or all BCV devices from one existing device group to another existing device group. The source and destination groups can be of different types. When moving a BCV device from one group to another, you can choose to have the device's logical name renamed to the default naming convention of the destination group. This helps to avoid naming conflicts that may be encountered.

Other options are available to limit a move to the devices that meet a specified set of criteria, which can be specified along with the **moveall** action. For a full description of these options, refer to **symbov** in the *EMC Solutions Enabler CLI Command Reference*.

Moving a specific device

To move BCV device **BCV001** from device group **prod** to the destination group **NewGroup** and rename the moved device, enter:

```
symbcv -g prod move ld BCV001 NewGroup -rename
```

Moving all BCV devices

You can move all local BCV devices from one device group to another device group. The source and destination groups can be of different types.

To move all BCV devices that are visible to your host from device group **prod** to device group NewGroup, enter:

symbcv -g prod moveall NewGroup

Moving remote BCV devices

Remote BCV devices can be moved from one device group to another device group. The following options allow all remote BCV devices of a specific type to be moved:

- -rdf specifies remote attached BCVs (RBCVs).
- -bcv specifies remote BCVs that mirror local BCVs (BRBCVs). This option must be used with the -rdf option.
- -rrdf specifies BCVs that are remotely associated with remote BCVs (RRBCVs).
- -hop2 specifies BCV devices (2BCVs) that are remotely associated on the second hop of a cascaded SRDF configuration.

Removing devices

The **symbcv** command also contains a remove all action (**rmall**), which will remove all devices meeting the specified criteria from the specified device group.

Managing BCV devices with composite groups

When adding BCV devices to a composite group, consider the following:

- The user must specify a local array ID.
- If no devices have been added to the composite group yet, and if there is only one RDFG on the array, then that RDFG is assumed; otherwise, you must specify a RDFG when adding remote BCVs.
- The -host, -SA, and -P parameters are only valid when associating local BCV devices.
- If -bcv is specified, the BCV list affected is the BRBCV list (or the BCV of the remote BCV device).
 NOTE:

-rdf is required when -bcv is specified.

- If **-rdf** is specified and **-bcv** is not specified, the BCV list affected is the RBCV list.
- If -rrdf is specified, the BCV list affected is the RRBCV list.
- If -hop2 and -remote_rdfg are specified, the BCV list affected is the 2BCV list.
- If -rdf and -bcv and -rrdf are not specified, the BCV list affected is the BCV list.

Associating BCV devices with a composite group

Use the following syntax to associate a BCV using the given device name to the composite group:

```
symbcv -cg CgName -sid SymmID [[-rdf [-bcv]] | [-rrdf] | [-hop2]] [-rdfg GrpNum [-
remote_rdfg RemoteGrpNum]] associate dev SymDevName [LdevName]
Use the following syntax to associate all BCV devices for the SymmID to the composite
group:
symbcv -cg CgName -sid SymmID [[-rdf [-bcv]] | [-rrdf] | [-hop2]] [-rdfg GrpNum [-
remote_rdfg RemoteGrpNum]] associateall [pd | -host HostName] [-sid SymmID]
[-SA # | ALL] [-p #] [-N #]
[-cap # [-captype mb | cyl]]
[-rdf [-loce]]
[-sel_rdfg SelRdfGrpNum]
[-devs <SymDevStart:SymDevEnd | SymDevName</pre>
```

```
[,<SymDevStart:SymDevEnd | SymDevName>...]>]
```

Disassociating BCV devices from a composite group

Use the following syntax to disassociate a BCV using the device name:

symbov -cg CgName -sid SymmID [[-rdf [-bcv]] | [-rrdf] | [-hop2]] [-rdfg GrpNum [remote rdfg RemoteGrpNum]] disassociate dev SymDevName [-force]

Moving BCV devices to a composite group

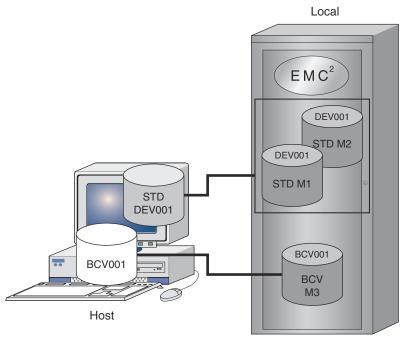

Use the following syntax to move the BCV that has the given device name to the destination composite group:

```
symbcv -cg CgName -sid SymmID [[-rdf [-bcv]] | [-rrdf] | [-hop2]] [-rdfg GrpNum [-
remote rdfg RemoteGrpNum]] move dev SymDevName DestCgName [-force]
```

Establishing BCV pairs

After configuration and initialization of an array, BCV devices contain no data. The BCV devices, like the standard devices, have unique host addresses and are online and ready to the hosts to which they are connected. The full establish must be used the first time the standard devices are paired with BCV devices.

Initial BCV configuration on page 107 illustrates the initial configuration prior to performing any TimeFinder BCV operations. In this figure, the host views the M1/M2 mirrored pair as a single standard device (DEV001) and the BCV device as BCV001.

SYM-001491

Figure 30. Initial BCV configuration

To obtain a copy of the data on a standard device, a BCV pair must be established. A BCV pair consists of a BCV device and a standard device. The standard device can have various mirror structures (unprotected, two-way or three-way mirrored, RAID, RAID with SRDF), as long as the number of mirrors does not exceed three. This constraint is in place because establishing a BCV pair requires assigning the BCV device as the next available mirror of the standard device.

Since there is a maximum of four mirrors allowed per device in the array, a device already having four mirrors is not able to accommodate another one.

Optionally, you can target devices in a device group, composite group, or device file:

symmir -g DgName -full establish

symmir -cg CgName -full establish

symmir -f[ile] FileName -full establish

To initiate a full establish on all the BCV pairs in the **prod** device group, enter:

symmir -g prod -full establish

To initiate a full establish on one BCV pair, **DEV001**, in the **prod** device group, enter:

symmir -g prod -full establish DEV001

To initiate a full establish on more than one BCV pair (list) in the **prod** device group with one command, enter:

symmir -g prod -full establish DEV001 BCV 1d BCV005 DEV002 BCV 1d BCV007 DEV003 BCV 1d BCV008

Fully establishing a BCV pair on page 108 illustrates the full establish of a BCV pair.

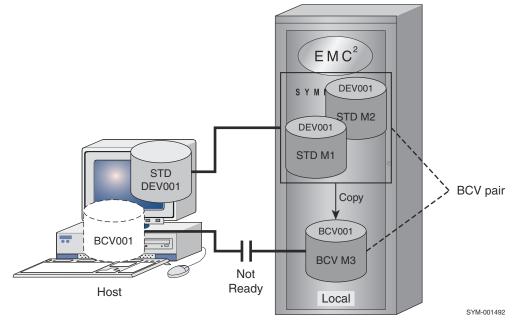

Figure 31. Fully establishing a BCV pair

When a full establish is initiated for each specified BCV pair in a device group:

• Command validity is checked. For example, the array makes sure that both the standard device and the BCV device are the same size, the device specified as the BCV has the BCV attribute, the standard device does not already have a BCV device assigned to it, and so on.

If the standard device is a metahead device, the BCV must also share the same metadevice properties. All metamembers will be implicitly established along with the metahead device.

- The BCV device is set as Not Ready to the host.
- The BCV device is assigned as the next available mirror of the standard device. A BCV can be the second, third, or fourth mirror of the standard device. For example, in Fully establishing a BCV pair on page 108, it is the third mirror (M3).
- The contents of the standard device are copied to the BCV. For example, in Fully establishing a BCV pair on page 108, the BCV device receives its data from both the first fully valid mirror of the source.

The BCV pair is synchronized when the standard device mirrors and the BCV mirror contain identical data.

() NOTE:

The BCV device is not available for host use during the time that it is assigned as a BCV mirror on a standard device. However, any new data written to the standard device is copied to the BCV device while the BCV pair exists. By default, Solutions Enabler rejects establish commands for CKD online devices. You can allow the establish command for CKD online devices by disabling the SYMAPI_TF_CHECK_ONLINE_CKD option. For instructions on disabling or enabling this option, refer to the *EMC Solutions Enabler Installation Guide*.

Specifying the default method for establishing BCV pairs

When specifying the default method for establishing BCV pairs, you can either set it at the system level by using an options parameter, or at the user level by using an environment variable.

() NOTE:

User level settings (environment variables) will override system level settings (options file parameters).

() NOTE:

Because of the load that establish operations place on an array, you should only change these settings under the direction of EMC. Please contact your EMC representative before changing these settings.

Specifying at the system level

To specify the default method for establishing BCV pairs at the system level, set the SYMAPI_DEFAULT_BCV_ESTABLISH_TYPE parameter in the **options** file. Possible values are:

- SINGULAR specifies to issue an establish to a single device, including a metamember, at a time. This method allows other tasks access to the array when doing a large number of establishes.
- PARALLEL (default) specifies to issue an establish to each servicing disk adapter (DA) in parallel, and then wait for a DA to finish before issuing another establish to that DA.
- SERIAL specifies to issue establishes as fast as the Global Special Task (GST) queue can handle them. However, all members
 of a meta must be established before continuing to the next meta or device. This is the default method when using
 metadevices.

() NOTE:

The EMC Solutions Enabler CLI Command Reference contains information on changing the **options** file parameters.

Specifying at the user level

To specify the default method for establishing BCV pairs at the user level, set the SYMCLI_BCV_EST_TYPE environment variable. Possible values for this variable are SINGULAR, PARALLEL, or SERIAL, as described earlier.

When specifying the default method as SINGULAR or PARALLEL, you can also set the SYMCLI_BCV_EST_DELAY environment variable to specify how long to wait between sending commands to the array. Possible value for this variable range from 0 to 30, with 0 being the default setting.

(i) NOTE:

The EMC Solutions Enabler CLI Command Reference contains information on changing environment variables.

Instantly establishing multiple BCV pairs

The multi/instant establish option improves the performance of a typical establish operation by submitting multiple BCV pairs in a single system call to be established instantly.

You can enable (default)/disable this feature with the SYMAPI_TF_MULTI_ESTAB_REST environment variable. Setting the SYMAPI_DEFAULT_BCV_ESTABLISH_TYPE parameter to SERIAL or SINGULAR will cause this option to be ignored.

Establishing multiple BCVs with a single standard device

You can fully establish (at different times) up to 16 BCV devices (8 when using emulation mode) associated with a single standard device. The BCV devices must also be associated to the same device group.

(i) NOTE:

Using the environment variable SYMCLI_MAX_BCV_PAIRS, the maximum number of pairs (established or restored) can be adjusted between 1 to 16 BCV devices.

With this feature, standard devices retain a relationship with multiple BCVs as long as those BCVs do not become paired with another standard. Here, the information about changed tracks is saved for a split BCV device when another BCV device is subsequently established and split from the same standard device. By invoking a series of split and -full establish commands over time (as shown in Establishing a multi-BCV environment on page 110), a multi-BCV environment becomes established that retains progressive historical images of the specified standard.

() NOTE:

When the maximum number of multi-BCV pairs is reached, you can alter the BCV pair cancel policy that controls the round-robin device usage as you fully establish the next device beyond the set maximum pair count. Using environment variable SYMCLI_BCV_PAIR_POLICY, you can cancel the incremental relationship between the STD and the oldest BCV (default), cancel the newest, or don't cancel any BCV in the set.

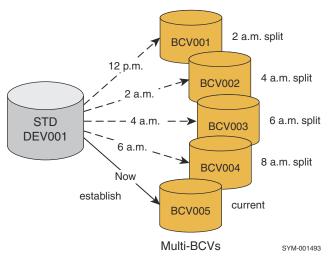

Figure 32. Establishing a multi-BCV environment

To fully establish the standard with BCV005, enter:

```
symmir -g prod split DEV001
symmir -g prod -full establish DEV001 BCV 1d BCV005
```

In this environment, you can specify any one of these older BCVs to incrementally restore the standard back to a historical copy.

Canceling a multi-BCV relationship

You can completely cancel the incremental relationship between the STD and any one of the split multi-BCV devices from the set using the cancel operation. This operation will put the BCV in either of the following states, depending on whether you are running TimeFinder in native or emulation mode:

Table 13. BCV state

| TimeFinder mode | BCV state |
|-----------------|-----------------|
| Native | SplitNoInc |
| Emulation | Never Establish |

You cannot incrementally establish or incrementally restore that BCV pair again until you have performed another full establish operation or a full restore operation.

To remove BCV001 from the set, enter:

symmir -g prod cancel DEV001 BCV ld BCV001

As shown in Canceling a multi-BCV on page 111, once you cancel the specified BCV, all records of track changes between the STD and the canceled BCV are destroyed.

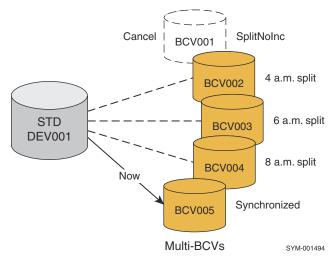

Figure 33. Canceling a multi-BCV

SRDF-connected BCV pairs

You can specify an establish action to a remote array using the RDF flag (-rdf), which fully establishes the remote BCV pairs.

To perform a full establish operation in the remote array at site B when the RDF flag is specified, use the following command:

symmir -g prod -rdf -full establish

To initiate a full establish on one remote BCV pair, DEV001, in the prod group, enter:

symmir -g prod -rdf -full establish DEV001 bcv ld RBCV001

In this case, the flag indicates that the BCV device being established is an SRDF-connected BCV device, which will be established with the remote mirror of the local RDF standard device.

To perform a full establish operation in the remote array at site B when the RDF and BCV flags (-rdf and -bcv) are specified, use the following command:

symmir -g prod -rdf -bcv -full establish

To initiate a full establish on one remote BCV pair, BCV001, in the **prod** group, enter:

symmir -g prod -rdf -bcv -full establish BCV001 BCV ld BRBCV001

In this case, the **-rdf** parameter indicates that the BCV device being established is an SRDF-connected BCV device, which will be established with the remote standard mirror of the local R1 BCV device.

Second-level remote BCV pairs

You can specify an **establish** action to a second remote site using the remotely attached remote BCV flag (**-rrbcv** option), which fully establishes second-level remote BCV pairs. To perform a full establish operation in the remote array at site C when the remotely attached remote BCV flag (**-rrbcv** option) is specified, use the following command:

```
symmir -g prod -rrbcv -full establish
```

To initiate a full establish on one remote BCV pair, RBCV001, in the **prod** group, enter:

symmir -g prod -rrbcv -full establish RBCV001 BCV ld RRBCV001

In this case, the flag indicates that the BCV device being established is a second hop SRDF-connected BCV device, which will be established with the remote standard mirror of the remote BCV device.

Hop 2 BCV pairs in a cascaded SRDF configuration

You can specify an **establish** action to an array located at the tertiary site of a cascaded SRDF configuration.

To perform a full establish operation in the remote array at the tertiary site (C) when the hop 2 flag is specified, use the following command:

symmir -g prod -hop2 establish -full

In this case, the flag indicates that the SRDF-connected BCV device (2BCV001) is being established with the remote partner of the R21 device, which is the remote partner of the local RDF standard device.

Using cascaded Clone Emulation to cascaded clone (Enginuity 5876)

In environments running Enginuity 5876, the target device of a Clone Emulation session can be used as the source for one or more clone sessions and vice versa:

- Clone session to a Clone Emulation session
- Clone Emulation session to a clone session

Performing an incremental restore to a cascaded clone target is supported. For example, devices in an A -> B -> C cascaded clone session can copy data from device C to device A.

Clone session to a Clone Emulation session

In this configuration, the source device A to target device B is a TimeFinder/Clone session, and source device B to target device C (BCV) is a TimeFinder/Clone Emulation session.

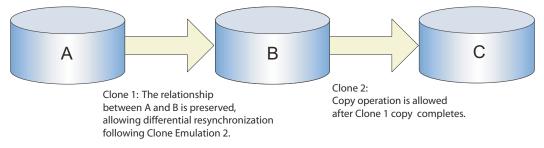

Figure 34. Cascaded Clone to a cascaded Clone Emulation session

Clone and B to C TimeFinder/Clone Emulation states on page 112 lists the Clone-to-Clone Emulation target session states.

() NOTE:

When A→B session is SynclnProgress or RestoreInProgress, the -symforce flag is required when performing a B→C split operation.

| B→C session state | Clone A → Clo | Clone A \rightarrow Clone B \rightarrow Clone C session state | | | | | |
|----------------------|---------------|---|---------|---------------------------|--------------|---------------|----------|
| | A→B | A→B | A→B | A→B | A→B | A→B | A→B |

Clone Emulation session to a clone target session

In this configuration, the source device A to target device B (BCV) is a TimeFinder/Clone Emulation session, and source device B to target device C is a TimeFinder/Clone session. Clone Emulation and clone target session states on page 114 lists the Clone Emulation to Clone target session states.

() NOTE:

When $A \rightarrow B$ session is SynclnProgress or RestoreInProgress, the -symforce flag is required when performing a $A \rightarrow B$ split.

Table 15. Clone Emulation and clone target session states

Establishing concurrent BCV pairs

When you establish a BCV device as a mirror of a standard device, that relationship is known as a BCV pair. When you sequentially establish/split/establish a number of BCV devices over time with a specified standard, that is known as a multi-BCV relationship.

You can establish two BCV devices (eight when using emulation mode) as concurrent mirrors of a single standard device all within the same **symmir** command line. This relationship is known as a concurrent BCV pair. This feature allows you or an application script to instantly generate two synchronized copies of the standard data. When the two BCVs are split from the standard, the BCV's hosts can access the data on either BCV.

When establishing concurrent BCV pairs, you can either specify the BCVs, or use the **-concurrent** option to allow the array to select suitable (in terms of size, emulation, etc.) BCV(s) from the available BCV list.

Example: Specifying the BCVs

To concurrently establish BCV001 and BCV002 with standard DEV012 in device group CncGrp, enter:

```
symmir -g CncGrp establish -full DEV012 bcv ld BCV001
```

DEV012 bcv ld BCV002

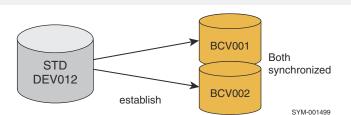

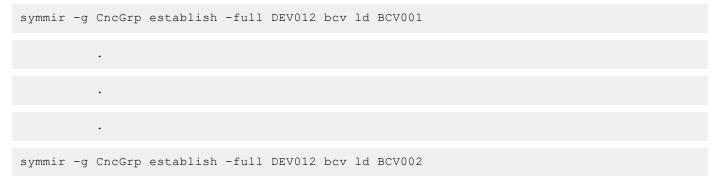

Figure 35. Establish concurrent BCV pairs

After the concurrent BCVs become split at some point, you can then concurrently resynchronize the BCVs with an incremental establish:

```
symmir -g CncGrp establish DEV012 bcv ld BCV001
DEV012 bcv ld BCV002
```

While these examples pair both BCVs at the same time, you can also establish the first BCV device now and the second one later. In either case, the concurrent BCVs become synchronized to the standard and remain that way until you split the BCVs from the standard.

The following is a valid concurrent BCV pair example, provided there is no split action between these commands:

Example

To instruct the array to select suitable BCV(s) to concurrently establish with standard DEV012 in device group CncGrp, enter:

symmir -g CncGrp establish -full DEV012 -concurrent

In this case, if the standard is already synchronized with one BCV, the array will synchronize one other BCV with it. If the standard device is not yet synchronized with a BCV, the array will still only synchronize one BCV with it.

Performing a protected BCV establish (moving all mirrors)

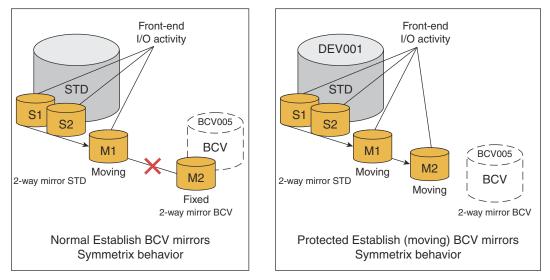

The protected BCV establish (**-protbcvest**) option (also called the moveall establish) can be used with the establish action to move all mirrors of locally mirrored BCV devices to join the mirrors of the standard device. This protected BCV moving mirror feature improves the availability of the BCV mirrors, particularly after a split operation where all BCV mirrors are instantly

synchronized. This feature, also known as instant BCV mirror sync, is available with full or incremental establish or restore operations. This feature is only useful in a native TimeFinder environment.

() NOTE:

This feature is not supported if the standard device is a dynamic concurrent SRDF device or if TimeFinder is in emulation mode.

Establishing two-way BCV mirrors with protected establish on page 116 compares the array behavior between a normal and a moving protected establish action.

SYM-001500

Figure 36. Establishing two-way BCV mirrors with protected establish

In a 2-way BCV mirror configuration for a normal establish, M2 is fixed and can only be updated from M1 after a split. For a 2-way BCV mirror device for a protected establish, both M1 and M2 move to the standard device mirror set and become instantly synchronized and available for updates from I/O activity on the standard device.

To initiate a full **-protbcvest** establish on a 2-way BCV pair with 2-way standard **DEV001** in device group **Prod**, enter:

symmir -g Prod establish -full -protbcvest DEV001 BCV ld BCV005

For more information about the affects of **-protbcvest** during a split operation, refer to Splitting a protectively established BCV on page 124.

Incrementally establishing BCV pairs

Incrementally establishing a BCV pair accomplishes the same thing as the establish process, with a major time-saving exception: the standard device (DEV001) copies to the BCV device (BCV001) only the new data that was updated on the standard device while the BCV pair was split. Any changed tracks on the BCV are also overwritten by the data on the corresponding tracks on the standard device.

This process is useful if the data yielded from running an application on the BCV device is not needed or if a fresh copy of current data is needed.

Optionally, you can target devices in a device group, composite group, or device file:

```
symmir -g DgName establish
symmir -cg CgName establish
symmir -f[ile] FileName establish
```

Examples

To initiate an incremental establish on all the BCV pairs in the prod device group, enter:

symmir -g prod establish

To initiate an incremental establish on a BCV pair, DEV001, in the **prod** device group, enter:

symmir -g prod establish DEV001

To initiate an incremental establish on a list of specific BCV pairs in the **prod** device group, enter:

symmir -g prod establish DEV001 DEV002 DEV005

The establish defaults to re-establishing the previous BCV pairing, unless you use either the -full option.

Automatically converting an incremental establish to a full establish

TimeFinder will automatically convert an incremental establish to a full establish when it determines that the requested devices (local or remote) have no prior relationship.

The SYMAPI_DEFAULT_BCV_ESTAB_INC_TO_FULL parameter in the options file allows you to enable this feature. Disabling this feature (default) will cause the SYMAPI to return the error SYMAPI_C_DEVICE_IS_NOT_PAIRED, as it did with previous versions.

() NOTE:

Enabling the SYMAPI_DEFAULT_BCV_ESTAB_INC_TO_FULL parameter does not eliminate the requirement to use the **-full** option with the **-opt** option.

Incrementally establishing multiple BCV pairs

You can incrementally establish (at different times) up to 16 (8 when using emulation) BCV devices associated with a single standard device. Note that initially, all the BCV devices must have been fully established before you perform any incremental establishes on them.

(i) NOTE:

Using the environment variable SYMCLI_MAX_BCV_PAIRS, the maximum number of pairs (established or restored) can be adjusted between 1 to 16 BCV devices.

With this feature, standard devices retain a relationship with multiple BCVs as long as those BCVs do not become paired with another standard. Here, the information about changed tracks is saved for a split BCV device if another BCV device is subsequently incrementally established and split from the same standard device. By invoking a series of **split/increment establish** commands over time (Establishing a multi-BCV environment on page 118), a multi-BCV environment becomes established that retains progressive historical images of the data on the specified standard.

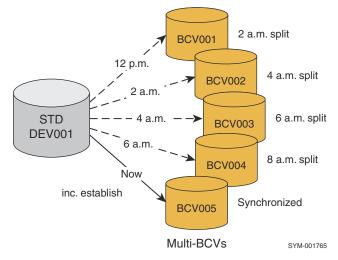

Figure 37. Establishing a multi-BCV environment

To query for existing multi-BCVs that were originally all previously (full) established, and then to incrementally establish **BCV005** with the standard, enter:

```
symmir -g DgName query -multi
symmir -g DgName split DEV001
symmir -g DgName establish DEV001 BCV 1d BCV005
```

In this environment, you can specify any one of these older BCVs to incrementally restore or establish the standard back to a historical copy.

SRDF-connected BCV pairs

You can specify an incremental establish action to a remote site using the RDF flag (-rdf option), which incrementally establishes the remote BCV pairs.

To perform an incremental establish operation in the remote array at site B when the -rdf option is specified, use the following command:

symmir -g prod -rdf -establish

In this case, the -rdf option indicates that the BCV device being established is an SRDF-connected BCV device, which will be established with the remote standard mirror of the local RDF standard device.

Second-level remote BCV pairs

You can specify an incremental establish action to a second remote site using the remotely attached remote BCV flag (-rrbcv option), which incrementally establishes second-level remote BCV pairs. An incremental establish operation in the remote array at site C when the remotely attached remote BCV flag (-rrbcv option) is specified with the following command:

symmir -g prod -rrbcv establish

To initiate an incremental establish on one remote BCV pair, **RBCV001**, in the **prod** group, enter:

symmir -g prod -rrbcv establish RBCV001 BCV ld RRBCV001

In this case, the flag indicates that the BCV device being established is a second Hop SRDF-connected BCV device, which will be established with the remote standard mirror of the remote BCV device.

Hop 2 BCV pairs in a cascaded SRDF configuration

You can specify an incremental establish action to an array located at the tertiary site of a cascaded SRDF configuration.

Perform an incremental establish operation in the remote at the tertiary site (C) when the hop 2 flag is specified with the following command:

symmir -g prod -hop2 establish

In this case, the flag indicates that the SRDF-connected BCV device is being established with the remote partner of the R21 device, which is the remote partner of the local RDF standard device.

Protected BCV incremental establish

The protected BCV establish (**-protbcvest**) option (also known as the moveall establish) can be used with the incremental establish action to move all mirrors of locally mirrored BCV devices to join the mirrors of the standard device. This moving of the mirrors feature improves availability of the BCV mirrors, particularly after a split operation where all mirrors are instantly synchronized.

To initiate a protected (**-protbcvest**) incremental establish on a 2-way BCV pair with 2-way standard **DEV001** in device group **Prod**, enter:

symmir -g Prod establish -protbcvest DEV001 BCV 1d BCV005

For more information about the protected BCV established environment, refer to Performing a protected BCV establish (moving all mirrors) on page 115.

Splitting BCV pairs

After an establish operation and the standard device and BCV mirrors are synchronized, the BCV device becomes a mirror copy of the standard device. You can split the paired devices to where each holds separate valid copies of the data, but will no longer remain synchronized to changes when they occur. SYMCLI processes can then be executed with the BCV device once the split completes.

Optionally, you can target devices in a device group, composite group, or device file:

```
symmir -g DgName split
symmir -cg CgName split
symmir -f[ile] FileName split
```

Examples

To split all the BCV pairs in the prod device group, enter:

```
symmir -g prod split
```

To split a BCV pair, DEV001, in the prod device group, enter:

symmir -g prod split DEV001

To split a list of standard devices in the prod device group, enter:

symmir -g prod split DEV001 DEV002 DEV003

Split the BCV pair on page 120 illustrates the splitting of a BCV pair.

(i) NOTE:

Relabeling devices is sometimes required in situations where devices are under an MS Windows type volume manager's control. If a BCV (TimeFinder) device holds an identical copy of its standard (paired) device, and when the BCV device becomes ready to the Windows operating system, the volume manager will detect two identical volumes with different mount points. This can cause the volume manager on Windows to exit and bring down a system.

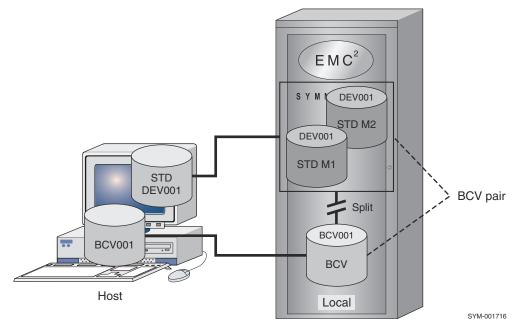

Figure 38. Split the BCV pair

When a split is initiated for each specified BCV pair in a device group, the following occurs:

- Command validity is checked. For example, the array makes sure that the standard device has an active BCV mirror and that the standard and BCV devices comprise a BCV pair.
- Any pending write transactions to the standard device and the BCV device are destaged.
- The BCV device is split from the BCV pair.
- If the device is a metadevice, all metamembers are implicitly split as well.
- The BCV device state is changed to Ready, enabling host access through its separate address (BCV001).
- Operation with the standard device is resumed and any tracks changed from write operations to the standard device are marked. (This is necessary for updating the BCV device if it is reestablished with the same standard device at a later time.)
- If the BCV device has any of its own mirrors, the mirrors are synchronized, unless protected establish or emulation is used. Once you finish running any Business Continuance processes on the BCV device, the following options are available:
- Incremental establish or reestablish of the BCV pair.
- Establish new using the same BCV devices with a different standard device.
- Restore data to a standard device from the BCV device.
- Incrementally restore data to the standard device from the BCV device (if the devices were previously paired).

SRDF-connected BCV pairs

About this task

You can specify a **split** action to a remote site using the RDF flag (-rdf option), which splits the remote BCV pairs.

To perform the splitting of a remote BCV pair, use the following command:

symmir -g prod -rdf split

In this case, the flag indicates that the BCV device being split is an SRDF-connected device, which will be split from the remote standard mirror of the local RDF standard device.

If a BCV device has its own mirrors (local or remote), these mirrors will become synchronized with its first mirror after the BCV pair is split.

Second-level remote BCV pairs

You can specify a split action to a second remote site using the remotely attached remote BCV flag (-rrbcv option), which splits second-level remote BCV pairs. To perform a split operation in the remote array at site C when the remotely attached remote BCV flag (-rrbcv option) is specified, use the following command:

symmir -g prod -rrbcv split

To initiate a split on one remote BCV pair, RBCV001, in the prod group, enter:

symmir -g prod -rrbcv split RBCV001 BCV ld RRBCV001

In this case, the flag indicates that the BCV device being split is a second HOP SRDF-connected BCV device, which will be split from the remote standard mirror of the remote BCV device.

Hop 2 BCV pairs in a cascaded SRDF configuration

You can specify a split action to an array located at the tertiary site of a cascaded SRDF configuration.

To perform an establish operation in the remote array at the tertiary site (C) when the hop 2 flag is specified, use the following command:

symmir -g prod -hop2 split

In this case, the flag indicates that the SRDF-connected BCV device (2BCV001) is being split from the remote partner of the R21 device, which is the remote partner of the local RDF standard device.

Remote copy with BCV split

In addition to splitting a local BCV pair, you can further specify the remote (-remote) option which makes the R1 device ready on the link and propagates the R1 BCV copy across the SRDF link to the R2 that mirrors the BCV:

```
symmir -g prod split DEV001 -remote
```

Performing a reverse split

The reverse (**-reverse**) option initiates a reverse data copy from the fixed BCV mirror to the primary (moving) mirror of the BCV upon the completion of the split operation.

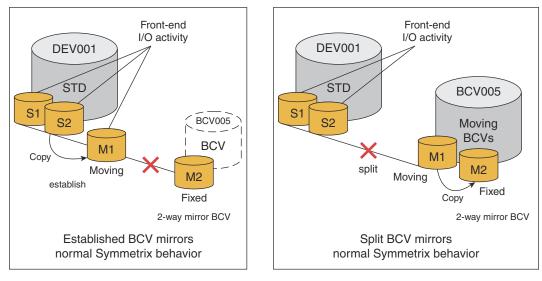

() NOTE:

A reverse split is not supported in TimeFinder/Clone Emulation mode.

Normal split behavior

Normally, when a BCV has two mirrors, only the primary mirror (M1) joins the standard device in establish or restore operations. As shown in Two-way mirror BCV establish/split normal behavior on page 122, the content of the primary BCV mirror is refreshed by data from the standard, when the BCV is established. The secondary BCV mirror (M2) is refreshed by data from the primary BCV mirror is split from the standard. The primary BCV mirror is referred to as the *moving mirror*, because it moves between the standard and the secondary (fixed) mirror.

Usually, after a split, the fixed BCV mirror is refreshed from the moving BCV mirror. This can either be a full copy operation or a differential copy. In a differential copy, only the tracks that have changed on the moving mirror during the time it was synchronized with the standard are refreshed.

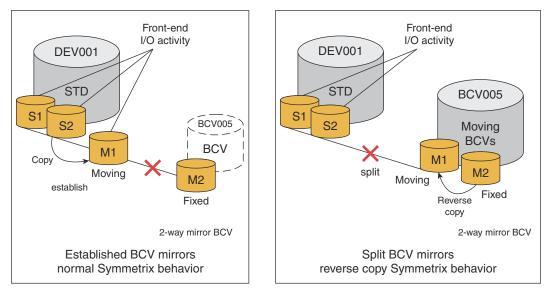

SYM-001722

Figure 39. Two-way mirror BCV establish/split normal behavior

Reverse split behavior

In a reverse split operation, the direction of data flow between the BCV mirrors is reversed. As shown in Two-way mirror reverse establish/split behavior on page 122, during a reverse split, the fixed BCV mirror (M2) will refresh the moving mirror (M1) after the split operation. This behavior may be desirable when you need to revert to an older copy of the data that was on the BCV before it was established/restored with the standard.

SYM-001723

Figure 40. Two-way mirror reverse establish/split behavior

() NOTE:

Be sure this is the behavior you want before invoking the reverse split option since the primary BCV mirror data is refreshed with an older mirror of data.

A reverse split is permitted only if both BCV mirrors were completely synchronized before the moving BCV mirror was paired with the standard device. When you anticipate a need for future reverse split operations, the *-reverse* option is applied to an establish or restore operation. This option requests a verification check that the BCV's fixed mirror has valid data. You must verify that both mirrors are in the Ready state after the split.

To establish DEV001/BCV005 and later perform a reverse split on DEV001 in device group Prod, enter:

```
symmir -g Prod establish -reverse DEV001
symmir -g Prod split -reverse DEV001
symmir -g Prod verify -bcv_mirrors -ready
```

(i) NOTE:

Data may not be immediately available. Use the verify command to check that both mirrors are in the Ready state for the data to be available.

Practical use of a reverse split on page 123 illustrates a practical use of a reverse split. At midnight a split results in a good point-in-time copy of a database. At 10 a.m. a corruption is discovered in the database, necessitating a database recovery. At 10:30 a.m. a restore operation is initiated from the BCV copy. Because the good data is immediately available to the BCV pair, the recovery begins shortly after initiating the restore process. At 11:00 a.m. during the recovery, one of the logs re-corrupts the database.

Though the data on the BCV's moving mirror has changed during the recovery process, a reverse split can be initiated. At 11:20 a.m. the BCV's fixed mirror refreshes its moving mirror, providing access to the good midnight copy of the data.

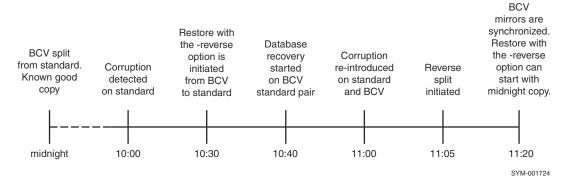

Figure 41. Practical use of a reverse split

Splitting concurrent BCV pairs

You can establish two BCV devices as concurrent mirrors of a single standard device. This relationship is known as a concurrent BCV pair. This feature allows you or an application to instantly generate two synchronized copies of the standard data (refer to Establishing concurrent BCV pairs on page 114).

When you apply a split action to a standard device that was concurrently established with two BCV mirrors, both BCVs become split from the standard.

To split concurrently established BCV001 and BCV002 with standard DEV012 in device group CncGrp, enter:

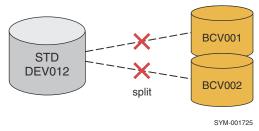

Figure 42. Splitting concurrent BCV pairs

Concurrent BCVs

If you do not want both of the concurrent BCVs to simultaneously split together, you can individually target the split action by explicitly specifying the BCV with the standard as follows:

```
symmir -g CncGrp split DEV012 bcv ld BCV001
```

or:

```
symmir -g CncGrp split DEV012 bcv ld BCV002
```

Concurrent splits

To display the status of the background concurrent split for both of these BCVs, enter:

```
symmir -g CncGrp query -multi -bg
```

Because invalid track tables are maintained, future concurrent incremental establish operations are possible on these split BCVs. After a concurrent split, it is possible to resynchronize just one BCV as follows:

symmir -g CncGrp establish DEV012

However, if you do not explicitly specify a BCV and you have not set an attachment preference, TimeFinder chooses the BCV to resynchronize, based on which of the two concurrent BCVs was split first.

You can also verify that the action has completed, as follows:

symmir -g CncGrp -split verify -bg DEV012 BCV 1d BCV002

Splitting a protectively established BCV

A split action splits both of the BCV mirrors away from the standard device that were previously established with a -protbcvest option. Split behavior on two-way BCV mirrors on page 124 illustrates the initial protected BCV established state and the resulting behavior of a split action on these BCV mirrors. For any split command, there is no need to apply the -protbcvest option to move all the mirrors away from the standard.

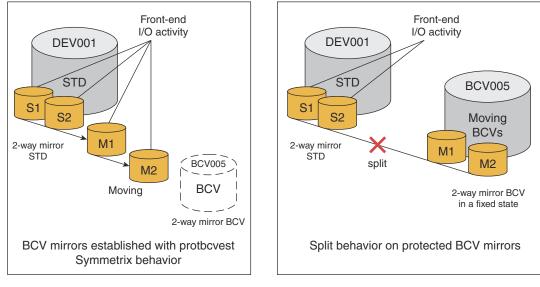

Figure 43. Split behavior on two-way BCV mirrors

SYM-001726

Before you split, you may need to query the array to examine the protected STD/BCV mirrored environment to identify the established moved devices for the split action, as follows:

```
symmir -g prod query -protbcvest
```

To perform a protected establish and later split (for example) on standard DEV001 with its BCV mirrors, in device group prod, enter:

| symmir | -g | prod | estab | lish | -protb | cvest | DEV001 |
|--------|----|------|-------|------|--------|-------|--------|
| | | | | | | | |
| | | | | | | | |
| • | | | | | | | |
| | | | | | | | |
| | | | | | | | |
| • | | | | | | | |
| | | | | | | | |
| | | | | | | | |
| • | | | | | | | |
| | | | | | | | |
| symmir | -g | prod | split | DEV(| 001 | | |

For more information about a protected BCV establish, refer to .

TimeFinder consistent split

TimeFinder consistent split allows you to split off a consistent, restartable copy of a database management system within seconds with no interruption to online service. Consistency split helps to avoid inconsistencies and restart problems that can occur when splitting a database-related BCV without first quiescing the database. Consistent split can be implemented using Enginuity Consistency Assist (ECA) functionality or SRDF/A.

Consistent split using Enginuity Consistency Assist on page 125 contains greater detail. The EMC Solutions Enabler SRDF Family CLI User Guide provides complete details on SRDF/A.

() NOTE:

With Enginuity 5876, TimeFinder includes the TimeFinder/Consistency Group (TimeFinder/CG) option. You do not need a separate license for TimeFinder/CG. The *EMC Solutions Enabler Version Installation Guide* provides all of the licensing information.

Consistent split using Enginuity Consistency Assist

About this task

You can use Enginuity Consistency Assist (ECA) to perform consistent split operations across multiple, heterogeneous hosts.

(i) NOTE:

With Enginuity 5876, TimeFinder includes the TimeFinder/CG option. You do not need a separate license for TimeFinder/CG.

Using ECA to consistently split BCV devices from the standards, you must have either a control host with no database or a database host with a dedicated channel to the gatekeeper devices. The dedicated channel cannot be used for servicing other devices to freeze I/O.

ECA consistent split on page 126 depicts how a control host can perform ECA consistent splits for three database hosts that access devices on an array.

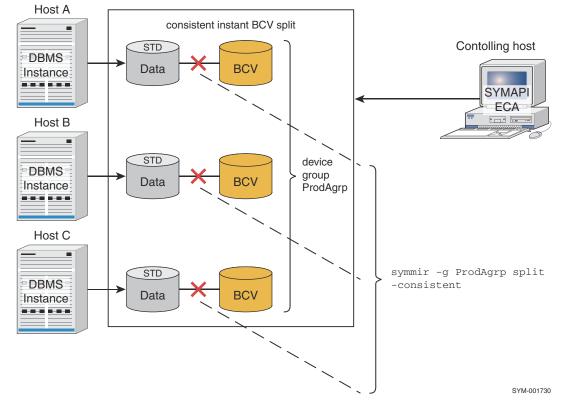

Figure 44. ECA consistent split

Device groups or composite groups must be created on the controlling host for the target database to be consistently split. Device groups can be created to include all of the devices being accessed or defined by database host access. For example, if you define a device group that includes all of the devices being accessed by Hosts A, B, and C (refer to ECA consistent split on page 126), then you can consistently split all of the BCV pairs related to those hosts with a single command. However, if you define a device group that includes only the devices accessed by Host A, then you can split those BCV pairs related to Host A without affecting the other hosts.

() NOTE:

For information on performing a consistent split to BCVs in both the local and remote arrays, refer to Consistent split for SRDF/A devices on page 127.

The following steps explain the example in ECA consistent split on page 126 of how to create one device group including all database host accessed devices and perform a consistent split operation on all of the BCV pairs accessed by those hosts.

Steps

1. Create a REGULAR type device group:

symdg create ProdAgrp -type REGULAR

2. Add all of the standard devices holding the database for each host (A, B, and C) to the device group:

```
symdg -g ProdAgrp addall -devs 0286:028B
symdg -g ProdAgrp addall -devs 0266:026B
symdg -g ProdAgrp addall -devs 0246:024B
```

3. Associate the BCV devices that will hold the restartable copy of the database with the device group:

```
symbor -g ProdAgrp associateall -devs 039A:039F
symbor -g ProdAgrp associateall -devs 037A:037F
symbor -g ProdAgrp associateall -devs 035A:035F
```

4. Fully establish all BCV pairs in the device group:

symmir -g ProdAgrp establish -full -noprompt

() NOTE:

When the BCV pairs in device group ProdAgrp (Host A, B, and C - BCV pairs) are synchronized, you can perform the consistent split using the **symmir split** command to split all of the BCV pairs associated with those hosts.

5. Use the -consistent option to perform a consistent (instant) split on all BCV pairs in the device groups:

symmir -g ProdAgrp split -consistent

Once the symmir split -consistent command is issued, I/O to the device group is frozen and a 30-second Enginuity protection timer begins. After the split completes (or 30 seconds passes, whichever comes first), the I/O channels are thawed, granting (pent up) operations access to the standard devices. Splits across all devices in a group are considered consistent, if the BCV split execution is performed within that window.

If for some unknown host or I/O channel reason, not all devices are split within the 30-second window, **symmir** returns the following reply at completion:

Consistency window was closed on some devices before the operation completed.

At this point, the final successful split outside the window is no longer considered to be consistent in execution across the device group. For consistency and reliability sake, it is recommended that you reestablish the device group, and then (later) attempt the consistent split again.

Consistent split for SRDF/A devices

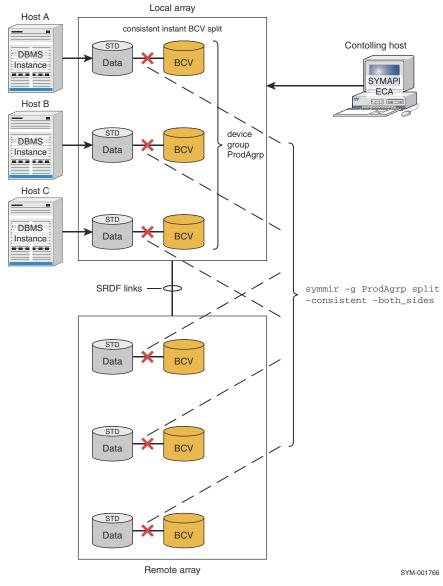

TimeFinder consistent split allows you to consistently split BCVs from R2 devices operating in asynchronous mode (SRDF/A).

Although not required for SRDF/A mode, it is recommended that you use TimeFinder BCVs at the remote site to mirror R2 devices and preserve a consistent image of data before resynchronization operations. Also, R2 device BCVs can be split off of the R2 without having to drop the RDF links and without disruption to the SRDF/A operational cycles. R2 BCVs can be controlled from the R1-side or the R2-side host as long as the device groups have been defined on that host. Controlling the R2 BCVs from the R1-side host requires using the symmir command with the -rdf option. To consistently split BCVs off the R2 RDF/A device in group **prod** from the R1 host, enter:

```
symmir -g prod split -rdf -consistent
```

Split both local and remote RDF devices (-both_sides)

In an RDF environment as shown in Consistent splits on both SRDF sides using ECA on page 128, you can perform a consistent split to the BCVs in both the local and remote arrays.

Restrictions: splitting devices on both local and remote arrays

In the preceding example, symmir -g GroupName split - consistent -both_sides split devices on both the local and remote arrays. For the host to perform this operation:

- The SRDF links must be up,
- The RDF mode must be synchronous, and
- The devices must have an RDF state of Synchronized.

Fully restoring BCV pairs

Like the full establish operation, a full restore operation copies the entire contents of the BCV devices to the standard device. Optionally, you can target devices in a device group, composite group, or device file:

```
symmir -g DgName -full restore
```

```
symmir -cg CgName -full restore
symmir -f[ile] FileName -full restore
```

Examples

To initiate a full restore on all the BCV pairs in the prod device group, enter:

```
symmir -g prod -full restore
```

To initiate a full restore on a BCV pair, DEV001, in the prod device group, enter:

symmir -g prod -full restore DEV001

To initiate a full restore on more than one (list) of BCV pairs in the prod device group, enter:

| symmir -g prod -full restore | DEV001 BCV ld BCV001 |
|------------------------------|----------------------|
| | DEV002 BCV ld BCV002 |
| | DEV005 BCV ld BCV003 |

The restoration process (Full restore of the BCV pair on page 129) is complete when the standard device and BCV device contain identical data.

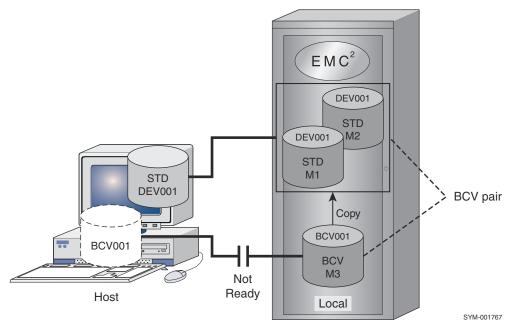

Figure 46. Full restore of the BCV pair

() NOTE:

The BCV device is not available for host use during the time that it is assigned as a BCV mirror on a standard device. However, unless the -protect option is used, any new data written to the standard device is copied to the BCV device while the BCV pair exists.

When a full restore is initiated for each specified BCV pair in a device group:

- Command validity is checked. For example, the command is rejected if the BCV device and the standard device are not the same size.
- The BCV device is set as Not Ready to the host.
- The BCV is assigned as the next available mirror of the standard device.

• The contents of the BCV device are copied to the standard device. For example, in Full restore of the BCV pair on page 129, the array copies the contents of M3 to both M1 and M2, overwriting the data present on those devices.

To use a BCV device for Business Continuance procedures, you must again split the BCV pair to make the BCV device available to its host. If you want to use a fully synchronized copy of the data, suspend all applications that are using the standard device, and make sure that all host buffering and intermediate caching is flushed to the appropriate device on the array prior to performing the split operation. If you do not require a synchronized copy of the data for running a Business Continuance process, this step is unnecessary.

Note that the base tasks performed with **symbov** such as list, associate, and disassociate locally or remotely connected BCV devices, are described at the beginning of this chapter.

By default, Solutions Enabler rejects restore commands for CKD online devices. You can allow the restore command for CKD online devices by disabling the SYMAPI_TF_CHECK_ONLINE_CKD option. For instructions on disabling or enabling this option, refer to the *EMC Solutions Enabler Installation Guide*.

Specifying the default method for restoring BCV pairs

The SYMAPI_DEFAULT_BCV_RESTORE_TYPE parameter in the options file enables you to specify the default method for restoring BCV pairs. Valid values are:

- SINGULAR specifies to issue the restore to one device at a time. This method allows other tasks access to the array when doing a large number of restores.
- PARALLEL (default) specifies to issue the restore to each servicing DA in parallel, and then wait for a DA to finish before issuing another restore to that DA.
- SERIAL specifies to issue restores as fast as the GST queue can handle them. However, all members of a meta must be restored before continuing to the next meta or device. This is the default method when using metadevices.
 NOTE:

The EMC Solutions Enabler CLI Command Reference contains information on changing the option file parameters.

Instantly restoring multiple BCV pairs

The multi/instant restore option improves the performance of a typical restore operation by submitting multiple BCV pairs in a single system call to be restored instantly.

You can enable (default)/disable this feature with the SYMAPI_TF_MULTI_ESTAB_REST environment variable. Setting the SYMAPI_DEFAULT_BCV_RESTORE_TYPE to SERIAL or SINGULAR will cause this option to be ignored.

SRDF-connected BCV pairs

You can also specify a full **restore** action to a remote site using the -rdf option, which fully restores the remote BCV pairs.

To perform a full restore operation in the remote array at site B when the RDF flag is specified with the following command:

```
symmir -g prod -rdf -full restore DEV001
```

In this case, the flag indicates that the BCV device being restored is an SRDF-connected BCV device, which will be established with the remote standard mirror of the local RDF standard device.

To perform a full restore operation in the remote array at site B when the -rdf and -bcv options are specified, use the following command:

symmir -g prod -rdf -bcv -full restore BCV001

In this case, the flags indicate that the BCV device being restored is an SRDF-connected BCV device, which will be established with the remote standard mirror of the local R1 BCV device.

Second-level remote BCV pairs

You can specify a full restore action to a second remote site using the remotely attached remote BCV-rrbcv option, which restores second-level remote BCV pairs. To perform a restore operation in the remote array at site C when the -rrbcv option is specified, use the following command:

symmir -g prod -rrbcv restore -full

To initiate a restore on one remote BCV pair, RBCV001, in the **prod** group, enter:

symmir -g prod -rrbcv restore RBCV001 BCV ld RRBCV001 -full

In this case, the flag indicates that the BCV device being restored is a second Hop SRDF-connected BCV device, which will be established with the remote standard mirror of the remote BCV device.

Hop 2 BCV pairs in a cascaded SRDF configuration

You can specify a full restore action to an array located at the tertiary site of a cascaded SRDF configuration.

To perform a restore operation in the remote array at the tertiary site (C) with the **-hop2** option, use the following command:

symmir -g prod -hop2 restore -full

In this case, the -hop2 option indicates that the SRDF-connected BCV device (2BCV001) is being established with the remote partner of the R21 device, which is the remote partner of the local RDF standard device.

Performing a remote copy with restore

In addition to restoring the specified BCV pair, you can further specify the remote (-remote) option, which will propagate the restored copy from the BCV pair across the SRDF link from the R2 standard to its R1 BCV in one command step:

symmir -g prod restore -rdf -bcv -remote -full

(i) NOTE:

The-**remote** option is not supported for restoring from an R2 standard to an R1 BCV. Instead you should use the two step method.

() NOTE:

Be sure you want the R1 BCV device to be updated with the restored copy before issuing the -remote option along with this restore operation.

It is good practice to perform restore operation at the remote site in two command steps (restore the BCV pair first, and then restore the R1 from the R2):

```
symmir -g DgName restore -bcv -rdf -full
symrdf -g DgName restore -bcv
```

Incrementally restoring BCV pairs

The incremental restore process (Incremental restore the STD on page 132) accomplishes the same thing as the restore process with a major time-saving exception: the BCV (BCV001) copies to the standard device (DEV001) only the new data that was updated on the BCV device while the BCV pair was split. Any changed tracks on the standard device are also overwritten by the data on the corresponding tracks on the BCV device. This maximizes the efficiency of the synchronization process.

This process is useful if the results from running a new application on the BCV device were desirable, and the user wants to port the data and the new application to the standard device.

The following forms enable you to target devices in a device group, composite group, or device file:

```
symmir -g DgName restore
symmir -cg CgName restore
symmir -f[ile] FileName restore
```

To initiate an incremental restore on all the BCV pairs in the **prod** device group, enter:

```
symmir -g prod restore
```

() NOTE:

It might be desirable for your site to set external device locks on all standard and BCV devices you are about to restore; refer to Device external locks on page 98.

To initiate an incremental restore on a BCV pair, DEV001, in the **prod** device group, enter:

symmir -g prod restore DEV001

To initiate an incremental restore on more than one (list) BCV pair in the prod device group, enter:

symmir -g prod restore DEV001 DEV002 DEV003

Incremental restore the STD on page 132 illustrates an incremental restore of a BCV pair.

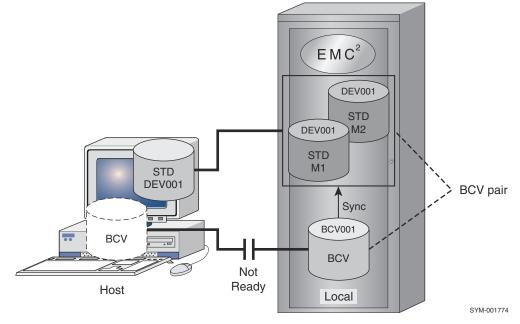

Figure 47. Incremental restore the STD

When an incremental restore is initiated for each specified BCV pair in a device group, the following occurs:

- Command validity is checked. For example, the command is rejected if the BCV device and the standard device were not previously paired.
- The BCV device is set as Not Ready to the host.
- The BCV device is assigned as the next available mirror of the standard device.
- The tracks are copied from the BCV device to the standard device. Any new data written to the BCV device while the BCV pair was split is written to the standard device. Any new data written to the standard device while the BCV pair was split is overwritten by the data on the corresponding track on the BCV device.

The BCV pair is synchronized when the standard device and the BCV device contain identical data.

(i) NOTE:

The BCV device is not available for host use while it is assigned as a BCV mirror on a standard device. However, any new data written to the standard device is copied to the BCV device while the BCV pair exists.

Multiple BCV pairs

You can incrementally establish or restore up to 16 BCV pairs (8 pairs when using emulation) associated with a single standard device. Using the environment variable SYMCLI_MAX_BCV_PAIRS, the maximum amount of pairs can be adjusted from 1 to 16 BCV devices. If a series of split/increment establish commands were invoked over time (refer to Incrementally establishing multiple BCV pairs on page 117), a multi-BCV environment becomes established that retains progressive historical images of the specified standard.

With the incremental restore command, you can specify any one of these older BCVs to incrementally restore the standard back to a specific historical copy. Restoring a BCV in a multi-BCV environment on page 133 shows the standard being restored by the **BCV002** copy, which was split at 4 a.m.

Before performing a restore, you may need to query the array to see which BCVs can be incrementally restored:

symmir -g DgName query -multi

() NOTE:

Before invoking the restore command, be sure this is the data copy you want your standard restored to since this BCV is an older version of what is current.

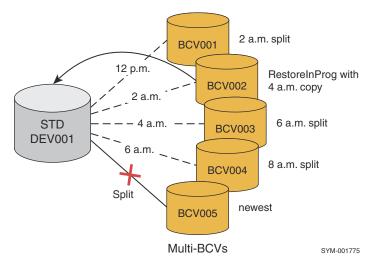

Figure 48. Restoring a BCV in a multi-BCV environment

To restore the current standard with old data from BCV002, enter:

symmir -g DgName split DEV001symmir -g DgName restore DEV001 BCV ld BCV002

SRDF-connected BCV pairs

You can also specify an incremental **restore** action to a remote site using the RDF flag (-rdf option), which incrementally restores the remote BCV pairs.

() NOTE:

Be sure you want the standard R1 device to be updated with the restored copy before issuing the -remote option along with this restore operation.

To perform an incremental restore operation in the remote array at site B when the RDF flag is specified, use the following command:

symmir -g prod -rdf restore

In this case, the flag indicates that the BCV device being restored is an SRDF-connected BCV device, which will be established with the remote standard mirror of the local R1 standard device.

In addition to restoring the specified BCV pair, you can further specify the remote (-remote) option, which will propagate the restored copy from the BCV pair across the SRDF link to the R1 standard.

() NOTE:

The -remote option is required when restoring to an R1 device that is ready on the link.

It is good practice to perform restore operations in two command steps (restore the BCV pair first, then restore the R1 from the R2):

```
symmir -g DgName restore -rdf
```

symmrdf -g DgName restore

Second-level remote BCV pairs

You can specify an incremental **restore** action to a second remote site using the remotely attached remote BCV flag (-rrbcv option), which incrementally restores second-level remote BCV pairs.

To perform an incremental restore operation in the remote array at site C specifying the remotely attached remote BCV flag (-rrbcv option), use the following command:

symmir -g prod -rrbcv restore

To initiate a restore on one remote BCV pair, RBCV001, in the **prod** group, enter:

symmir -g prod -rrbcv restore RBCV001 BCV ld RRBCV001

In this case, the flag indicates that the BCV device being restored is a second HOP SRDF-connected BCV device, which will be established with the remote standard mirror of the remote BCV device.

Hop 2 BCV pairs in a cascaded SRDF configuration

You can specify a incremental **restore** action to an array located at the tertiary site of a cascaded SRDF configuration.

To perform an incremental restore operation in the remote array at the tertiary site (C) specifying the hop 2 flag (-hop2 option), use the following command:

symmir -g prod -hop2 restore

In this case, the flag indicates that the SRDF-connected BCV device (2BCV001) is being established with the remote partner of the R21 device, which is the remote partner of the local RDF standard device.

Protecting BCV data during full or incremental restores

Once you initiate a restore from the BCV to the standard device, data from the BCV is immediately available to a host accessing the standard device. During the time the pair are joined, writes are sent to the standard and the BCV, while reads are satisfied by the data on the BCV if the data on the standard has not yet been completely updated from the BCV. However, this process can alter the BCV data during the restore operation. If you want to retain the original BCV data, use the protected restore feature.

The protected restore feature allows the contents of a BCV to remain unchanged during and after a restore operation, even while the BCV and the standard are joined. Subsequently, any writes to the BCV pair are not propagated to the BCV while the standard and the BCV are joined in a RestInProg or Restored state. This protection offers the same advantage as a reverse split, but without the need for a mirrored BCV.

You can restore data from a BCV to a standard device without altering the contents of the BCV, by using the protect(-protect) option. It write-disables the BCV mirror(s) during and particularly after the restore operation.

Examples

To initiate a protected full restore (for example) on the STD mirrors (DEV001) in the Prod group, enter:

symmir -g Prod -full restore -protect DEV001

To initiate a protected incremental restore (for example) on the STD mirrors (DEV001) in the Prod group, enter:

```
symmir -g Prod restore -protect DEV001
```

(i) NOTE:

If you ever need to split a device again that was protected restored, you must use the -protect option on the split command:

symmir -g Prod split -protect DEV001

To view device information for the protected restore operation, enter:

symmir -g Prod query -protect

() NOTE:

The standard invalid track count displayed in the query operation does not reflect any new writes while the device is in the RestInProg state. When the device state changes to Restored, the invalid track count displays as zero.

Cancelling BCV pairs

The symmin cancel command allows you to cancel a BCV pair relationship on a device by device basis, or for all the devices in a device group or composite group.

When operating in native TimeFinder, cancelling a BCV pair cancels the existing relationship between the specified standard and BCV device(s). Once the relationship is cancelled, the corresponding BCV devices go into the SplitNoInc state, and the BCV pair can no longer be incrementally established or restored.

When operating in emulation mode, cancelling a BCV pair terminates the relationship between the specified standard and BCV device(s). Once the relationship is terminated, the corresponding BCV devices go into the Never Established state, and the BCV pair can no longer be incrementally established or restored.

When cancelling a muli-BCV relationship, only the primary BCV is cancelled. For information on cancelling a multi-BCV relationship on page 110.

The following forms enable you to target devices in a device group, composite group, or device file:

```
symmir -g DgName cancel
symmir -cg CgName cancel
symmir -f[ile] FileName cancel
```

Examples

To cancel the BCV relationship for all the devices in the Prod group, enter:

symmir -g Prod cancel

To cancel a specific standard/BCV pair relationship in the Prod group, enter:

symmir -g Prod cancel DEV001 BCV dev 009C

To cancel the relationship of SRDF-connected BCV pairs in the Prod device group, enter any of the following:

symmir -g prod cancel -rdf

Cancels the relationship between the remote mirror device(s) and the remote BCV device(s).

symmir -g prod cancel -rdf -bcv

Cancels the relationship between the SRDF-connected BCV pair remotely mirroring the local BCV device.

symmir -g prod cancel -rrbcv

Cancels the relationship between the remote mirror of the remotely attached BCV device (RBCV) and the remotely attached remote BCV (RRBCV).

symmir -g prod cancel -hop2

Cancels the relationship between the remote mirror and the BCV (2BCV) two hops away in a cascaded SRDF configuration.

Querying BCV pairs

You can perform a query to determine the state of a BCV pair or all BCV pairs in a device group, composite group, or device file. The query is sent via the gatekeeper device to the array, returning with information about the state of the BCV pair(s).

The following forms enable you to target devices in a device group, composite group, or device file:

```
symmir -g DgName query
symmir -cg CgName query
symmir -f[ile] FileName query
```

Examples

To query the state of the BCV pairs in the prod device group, enter:

symmir -g prod query

To query the state of SRDF-connected BCV pairs in the **prod** device group, enter any of the following:

```
symmir -g prod query -rdf
symmir -g prod query -rdf -bcv
symmir -g prod query -rrbcv
symmir -g prod query -hop2
```

You can also obtain results using the -offline option, which looks at your configuration based on the host database.

The results of the query include the following information for each member of a BCV pair in a device group:

- Logical device name
- Device name
- Number of invalid tracks
- BCV pair state

To query the state of a split action on multi-BCVs or concurrent BCVs in a group **prod**, enter:

symmir -g prod query -multi

To query the state of any background split action on multi-BCVs or concurrent BCVs in a group prod, enter:

```
symmir -g prod query -multi -bg
```

To query the percent initiated on restore, establish, and split operations, enter:

symmir -g prod query -bg -percent

Using the -summary option

If you use the -summary option with the query argument, the results of the query will include the following information:

- Number of BCV pairs in each BCV pair state
- Number of invalid tracks
- Synchronization rate
- Estimated time to completion

The synchronization rate and estimated time to completion are shown only when -i or -c is specified and their has been a change in the number of invalid tracks since the previous iteration.

The -summary option also works with the **verify** argument.

Example

To view the number of BCV pairs in the **prod** device group that are in each state, and to view the estimated time to completion, enter:

```
symmir -g prod query -summary -i 60
```

Verifying BCV pair states

You can use the symmir verify command to verify whether one or all BCV pair(s) in a device group, composite group, or device file are in a particular state. The command can be used in scripts to guarantee that the BCV device pair(s) are in a Synchronized, Restored, or Split state prior to executing subsequent SYMCLI commands. If you do not specify any qualifiers with the symmir verify command, the default is to check for the Synchronized or Restored states.

The following forms enable you to target devices in a device group, composite group, or device file:

```
symmir -g DgName verify
symmir -cg CgName verify
symmir -f[ile] FileName verify
```

The following options qualify the symmir verify command. If you need to verify a concurrent BCV pair, include - concurrent with the option (for example, -synched -concurrent):

- -synched option verifies the Synchronized state.
- -syncinprog option verifies the SynclnProg state.
- -split option verifies the Split state. With an instant split, the system verifies the Split state immediately even though the background split is still in progress. To verify completion of a background split after an instant split, use the -split -bg option. Until the background split is complete, you cannot perform BCV control operations. You can use the -split -bg option to verify that the instant split is 100 percent complete in the background. For example:

symmir verify -g ProdBgrp -split -bg DEV001 bcv ld BCV002 -i 30

- -restored option verifies the Restored state. You can use the -restored -protect option to verify the Protected Restored state. In a concurrent BCV setup, you can use -restored -concurrent successfully only if the first BCV has already restored the standard and you are restoring now with the second BCV.
- -restinprog option verifies the RestInProg state.
- -bcv_mirrors option verifies that the mirrors of locally mirrored BCV devices are in the specified state. If you do not specify a state with this option, the default is to verify a Synchronized state.

Examples

For a multi-BCV or concurrent BCV device group, specifying the BCV on the command line ensures that the verify operation checks the status of the BCV. Otherwise, the verify operation checks the status of the standard device, which may no longer be established with the BCV that you want to verify. For example, the following command returns the status of standard device DEV002 with its last paired BCV:

symmir -g ProdBgrp verify DEV002

But the following command returns the status of a specific BCV pair (DEV002 with BCV001):

symmir -g ProdBgrp verify DEV002 BCV ld BCV001

The following command checks status every 30 seconds until all BCV pairs in the device group (ProdBgrp) or composite group (MyConGrp) are in the Synchronized or Restored state (the default when no state is specified on the command line):

symmir -g ProdBgrp -i 30 verify symmir -cg MyConGrp -i 30 verify

Possible outputs at 30-second intervals can be that none, not all, or all devices are synchronized or restored. The time to reach the Synchronized or Restored state varies with the number of devices being established or restored and the amount of data being copied.

The verify action returns a value of zero (code symbol CLI_C_SUCCESS) if the verify criteria are met, or one of the unique codes in Using options to verify a BCV mirror state on page 138 and Using options to verify a BCV pair state on page 139 if the verify criteria are not met:

Table 16. Using options to verify a BCV mirror state

| Options used with Verify | Code number | Code symbol |
|--------------------------|-------------|----------------------------|
| -bcv_mirrors | 4 | CLI_C_NOT_ALL_SYNCHRONIZED |
| -bcv_mirrors | 5 | CLI_C_NONE_SYNCHRONIZED |
| -bcv_mirrors -ready | 62 | CLI_C_NOT_ALL_READY |
| -bcv_mirrors -ready | 63 | CLI_C_NONE_READY |
| -bcv_mirrors -syncinprog | 27 | CLI_C_NOT_ALL_SYNCINPROG |
| -bcv_mirrors -syncinprog | 28 | CLI_C_NONE_SYNCINPROG |

Using composite groups to manage BCV pairs across arrays

About this task

A composite group is a user-defined group of devices that can span multiple arrays. This feature provides greater flexibility than a device group, which can define devices only on a single array. You can control specific BCV pairs within the composite group instead of having to operate on the entire group as in previous versions.

Using a composite group when a set of devices spans two arrays on page 140 illustrates a production host that is locally connected to two arrays (A and B). A composite group is defined on the production host and includes BCV pairs from each array. Another locally connected host allows you to access the BCVs once the BCV pairs are split.

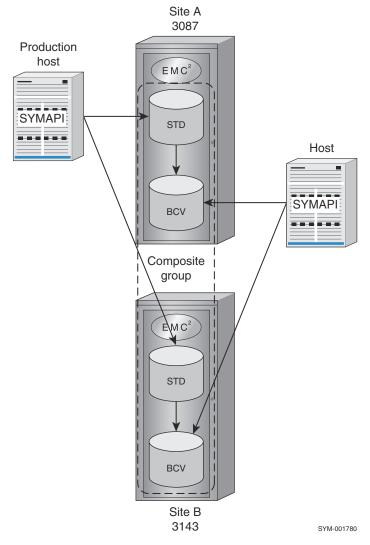

Figure 49. Using a composite group when a set of devices spans two arrays

Although TimeFinder control operations on BCV pairs might normally be performed from the production host (as shown in Using a composite group when a set of devices spans two arrays on page 140) because the composite group is defined there in its SYMAPI database, there are methods that would allow you to initiate copy sessions from another locally connected host. One way is to copy the composite group definition to another host. A more efficient method is to enable Group Name Services (GNS), which automatically propagates the composite group definition to the arrays and other locally attached hosts that are running the GNS daemon. For more information, refer to the *EMC Solutions Enabler Array Management CLI Product Guide.*

If you do not create each BCV pair explicitly, certain options such as -opt, opt_rag, and -exact allow you to control how multiple devices in a composite group are paired. Otherwise, a device-pairing algorithm checks if there were any previous pair assignments among the devices and, if not, pairs standards and BCVs of equal sizes.

Used only with a full establish operation, the optimize option that you choose depends on whether you are establishing local BCV pairs or remote BCV pairs. The -opt option is for local. It optimizes pairings across the local array without regard for whether the devices belong to different RDF (RA) groups. The -opt_rag option is for remote and requires the -rdf option. It uses optimization rules to create remote BCV pairs from devices within the same RDF (RA) group on an array.

The following steps outline the setup required for controlling a set of BCV pairs that spans two arrays as shown in Using a composite group when a set of devices spans two arrays on page 140:

Steps

1. From the production host, create a Regular type composite group (for example, MyGrp):

```
symcg create MyGrp -type regular
```

2. Add to the composite group those standard devices on array A (3087) and array B (3143) that are the source devices:

symcg -cg MyGrp -sid 3087 add dev 0076

symcg -cg MyGrp -sid 3143 add dev 0091

3. Add a BCV device from each array to the composite group:

symbov -cg MyGrp -sid 3087 associate dev 0051

symbov -cg MyGrp -sid 3143 associate dev 004F

4. Create the BCV pairs and initiate full copying from the standards to the BCVs:

symmir -cg MyGrp establish -full

5. When the BCV pairs are fully synchronized, you can split all BCV pairs in the composite group to access the BCVs:

symmir -cg MyGrp split

You can control specific BCV pairs within the composite group instead of having to control the group as a whole. To establish only the DEV001/ BCV001 pair from all devices in the composite group MyGrp:

symmir -cg MyGrp establish DEV001 bcv ld BCV001

Preferred attachment of BCVs (optional operations)

For advanced users, the preferred pair *attachment* (attach action) is an optional step in the management of BCV pairs that eliminates the need to specify a device for each subsequent full establish and full restore sequence in a script (for all Enginuity versions). It also applies to incremental establish and restore operations. It marks the specified BCV device as the preferred BCV to pair with the standard device.

After configuration and initialization of an array, BCV devices contain no data. The BCV devices, like the standard devices, have unique host addresses and are online and ready to the host(s) to which they are connected.

It is at this point, before any full establish or full restore operations are requested, you can validate your pairings as a preferred attachment before starting any data copy operations. The lists of individual standard devices and BCV devices can be examined, validated, and all devices sorted according to storage size, and subsequently, assigned as the preferred match (considering disk size) for attachment into BCV pairs.

(i) NOTE:

A full establish action with the optimize (-opt) or exact (-exact) option overrides the attach pairing scheme.

The following commands enable you to target devices in a device group, composite group, or a device file:

```
symmir -g DgName attach
symmir -cg CgName attach
symmir -f FileName attach
```

To initiate a preferred attachment on a BCV pair (DEV001) in the **prod** group, enter:

symmir -g prod attach DEV001 BCV ld BCV001

To initiate a preferred attachment on more than one BCV pair (list) in the **prod** group, enter:

| symmir -g prod attach | DEV001 BCV ld BCV001 |
|-----------------------|----------------------|
| | DEV002 BCV ld BCV002 |
| | DEV002 BCV ld BCV003 |

() NOTE:

The attach and detach preferred relationship are only known to the SYMAPI database on which you are operating.

The attach action checks command validity. For example, the array makes sure that both the standard device and the BCV device are the same size, the device specified as the BCV has the BCV attribute, the standard device does not already have a BCV device assigned to it, and so on.

If the standard device is a metahead device, then the BCV must also share the same metadevice properties. All metamembers are implicitly established along with the metahead device.

From this point forward, when you invoke the full establish or full restore control action with a BCV control operation, you will not need to specify the device names.

Detaching BCV preferences from devices

The **detach** action allows you to remove the preferred matched-pair association from the devices that was initially defined with the attach action.

The following forms enable you to target devices in a device group, composite group, or device file:

```
symmir -g DgName attach
```

symmir -cg CgName attach

symmir -f FileName attach

To detach the existing preferred attachment of various BCVs from their standard devices in the prod group, enter:

symmir -g prod detach

To detach the attached BCV preference on standard device (DEV001) in the prod group, enter:

symmir -g prod detach DEV001

Attaching remote devices as preferred pairs

For advanced usage, you can also specify an attach action to a remote site using the RDF flag (-rdf option), which attaches the remote mirror device(s) to the remote BCV device(s) as preferred pair(s).

To perform a preferred attachment operation in the remote array at site B with the RDF option (-rdf) specified, use the following command:

symmir -g prod -rdf attach DEV001 bcv ld RBCV001

In this case, the RDF flag indicates that the BCV device being attached is an SRDF-connected BCV pair, which will provide remote mirroring to the local standard device.

To perform an attach operation in the remote array at site B with the RDF and BCV options (-rdf and -bcv) specified, use the following command:

symmir -g prod -rdf -bcv attach BCV001 BCV 1d BRBCV001

In this case, the flags indicate that the BCV pair being attached is an SRDF-connected BCV pair, which provides remote mirroring to the local BCV device.

Detaching BCV preferences for remote devices

You can specify a **detach** preference action to a remote site using the RDF flag (-rdf option), which detaches the remote BCV(s) from the remote standard device(s) as preferred pair(s).

To perform a detach operation in the remote array at site B with the RDF option specified, use the following command:

symmir -g prod -rdf detach DEV001

In this case, the flag indicates that the preferred BCV device being detached is an SRDF-connected BCV, which provides remote mirroring to the local standard device.

To perform a detach operation in the remote array at site B with the RDF and BCV options (**-rdf** and -bcv) specified, use the following command:

symmir -g prod -rdf -bcv detach BCV001 BCV 1d BRBCV001

In this case, the flags indicate that the BCV pair being detached is an SRDF-connected BCV pair, which would provide remote mirroring to the local BCV device.

Attaching second-level remote devices as preferred pairs

You can specify an attach action to a second remote site using the remotely attached remote BCV flag (-rrbcv option), which attaches BCV preferences to second-level remote BCV pairs.

To perform an attach operation in the remote array at site C with the remotely attached remote BCV option (-rrbcv) specified, use the following command:

symmir -g prod -rrbcv attach

To initiate an attach on one remote BCV pair, RBCV001, in the **prod** group, enter:

symmir -g prod -rrbcv attach RBCV001 BCV ld RRBCV001

In this case, the flag indicates that the BCV device being attached is a second HOP SRDF-connected BCV device, which will be attached with the remote standard mirror of the remote BCV device.

Detaching BCV preferences from second-level remote devices

You can specify a **detach** action to a second remote site using the remotely attached remote BCV flag (-rrbcv option), which detaches BCV preferences from second-level remote BCV pairs.

To perform a detach operation in the remote array at site C with the remotely attached remote BCV option (-rrbcv) specified, use the following command:

symmir -g prod -rrbcv detach

To initiate a detach on one remote BCV pair, RBCV001, in the **prod** group, enter:

symmir -g prod -rrbcv detach RBCV001 BCV ld RRBCV001

In this case, the flag indicates that the BCV device being detached is a second HOP SRDF-connected BCV device, which will be detached from the remote standard mirror of the remote BCV device.

Attaching hop 2 devices as preferred pairs in a cascaded SRDF configuration

For advanced usage, you can specify an **attach** action to an array located at the tertiary site of a cascaded SRDF configuration.

To perform an attach operation in the remote array at the tertiary site (C) when the hop2 (-hop2 option) is specified with the following command:

symmir -g prod -hop2 attach DEV001 bcv ld 2BCV001

In this case, the flag indicates that the SRDF-connected BCV device (2BCV001) is being attached with the remote partner of the R21 device, which is the remote partner of the local RDF standard device.

Detaching BCV preferences from hop 2 devices in a cascaded SRDF configuration

For advanced usage, you can also specify an **detach** preference action to an array located at the tertiary site of a cascaded SRDF configuration.

To perform a detach operation in the remote array at the tertiary site (C) with the hop 2(-hop2 option) specified, use the following command:

symmir -g prod -hop2 detach DEV001 BCV ld 2BCV001

In this case, the flag indicates that the SRDF-connected BCV device (2BCV001) is being detached from the remote partner of the R21 device, which is the remote partner of the local RDF standard device.

Script summary for typical TimeFinder operations

About this task

The following is an example script of a set of typical operations using SYMCLI commands to manage a BCV environment:

Steps

1. Create a device group:

symdg create ProdBgrp

2. Add a standard device to a device group:

symdg -g ProdBgrp add pd c0t2d4

Repeat for all devices, or use RANGE, etc.

3. Associate a BCV device with a device group:

symbov -g ProdBgrp associate pd c4t2d4

Repeat for all BCVs.

4. Either establish the entire group:

symmir -g ProdBgrp -full establish -noprompt

Or establish explicitly:

symmir -g ProdBgrp -full establish DEV001 BCV 1d BCV001 -noprompt

Repeat this command for all pairs.

Transfer a different BCV device to the standard device:

- 5. Identify the established BCV pair.
- 6. Split the pair:

symmir -g ProdBgrp split DEV001 -noprompt

7. Select a new BCV to establish with the standard device:

symmir -g ProdBgrp -full establish DEV001 BCV ld BCV020 -noprompt

Script example for multi-BCV environment

About this task

The following is an example of a script for a multi-BCV environment:

You are tasked with testing business applications with incoming database data from certain anticipated peak periods in the day. Three copies of the database may be needed. To establish a multi-BCV environment, you must initially perform a full establish to each BCV device in the set.

Steps

1. For example, you plan to have BCV001 through BCV003 in the set to pair with DEV001 that is the source of your test data:

```
symmir -g MultigrpA -full establish DEV001 BCV 1d BCV001
symmir -g MultigrpA split DEV001 #split at 3:10pm
symmir -g MultigrpA -full establish DEV001 BCV 1d BCV002
symmir -g MultigrpA split DEV001 #split at 3:20pm
symmir -g MultigrpA -full establish DEV001 BCV 1d BCV003
```

2. It is now 4:00 p.m. and BCV003 is still currently established with DEV001. At this point, you are testing your business applications and want to reset your database back to the business activity that was current up till 3:10 p.m. To incrementally restore DEV001 to the 3:10 p.m. business data:

symmir -g MultigrpA split DEV001 #split at 4:00pm

symmir -g MultigrpA restore DEV001 BCV ld BCV001

3. You are now working successfully with the 3:10 p.m. data and want to continue test operations with this data and remove the second split BCV that occurred at 3:20 p.m. as this data will not be needed.

symmir -g MultigrpA cancel DEV001 BCV ld BCV002

4. You decide to call it a day, keeping the remaining two multi-BCVs and need to reestablish (incrementally establish) BCV003 to the current standard data:

symmir -g MultigrpA split DEV001 #split at 4:50pm symmir -g MultigrpA establish DEV001 BCV 1d BCV003

BCV pair states

When you invoke BCV control commands on a single BCV device, or on a group of BCV pair(s) using the symmir command, the BCV state is changed as illustrated in BCV pair states on page 146. You will see the abbreviated BCV pair state listed using the SYMCLI commands.

Table 18. BCV pair states

| BCV pair state | BCV pair state (abbreviated for display) | Description |
|----------------------|---|--|
| Never Established | NeverEstab | The BCV device is available for use, and was never established. Only the BCV device name is valid. |
| Sync In Progress | SyncInProg | When the Establish action is executed, data is copied from the standard device to the BCV device until both devices contain identical data. |
| Restore In Progress | RestInProg | When the restore action is executed, data is copied from the BCV to the standard device until both devices contain identical data. |
| Synchronized | Synchronized | The BCV and standard devices have identical data. Any changes to the standard device are also written to the BCV. The BCV is unavailable to the host for BC processing. |
| Restored | Restored | The BCV and standard devices have identical data, although the data was originally on the BCV before being synchronized. Any changes to the standard device are also written to the BCV. The BCV is unavailable to the host for BC processing. |
| Split in Progress | SplitInProg | The BCV devices are in the process of being separated, or split from the standard devices. |
| Split | Split | The BCV devices are completely separated, or split from the standard devices allowing each device to be accessed separately by the host. |
| Split No Incremental | SplitNoInc | The BCV devices are completely separated, or split from the standard devices but cannot be incrementally established or restored. |
| Split Before Sync | SplitBfrSync | The split occurred when a BCV device was synchronizing. The BCV device is separated from the standard device although the BCV device is not completely synchronized. |
| Split Before Restore | SplitBfrRest | The split occurred when a BCV device was being restored to a standard device. |

Table 18. BCV pair states (continued)

| BCV pair state | BCV pair state (abbreviated for display) | Description |
|----------------|---|---|
| | | The BCV device is separated from the standard device although the standard device is not completely synchronized. |
| Invalid | Invalid | Not all metamembers are in the same BCV state. |

Transient BCV pair states

When you initially invoke the symmir arguments for TimeFinder operations, BCV pairs enter a transient state and upon completion of the action, the BCV pairs enter a final BCV pair state (Actions for BCV devices on page 147).

Table 19. Actions for BCV devices

| Argument | Transient state | Final state | |
|-----------|-----------------|--------------|--|
| establish | SyncInProg | Synchronized | |
| split | SplitInProg | Split | |
| restore | RestInProg | Restored | |

BCV actions and applicable states

BCV control actions and applicable states on page 147 describes which BCV control operations can be invoked for a given BCV state. Invalid states can indicate that the devices in a BCV pair are in a different or *mixed* state. The -symforce option must be used (where noted in the table as F) to force a pair to a specified BCV state.

Table 20. BCV control actions and applicable states

| Contr ol Opera tion | Never Established | Sync in prog | Syncronized | SyncInProg | Split | Split no incremental | Split before sync | Split before restore | Restore in prog | Restored | Invalid |
|------------------------------|-------------------|--------------|-------------|------------|-------|----------------------|-------------------|----------------------|-----------------|----------|---------|
| esta blis h - full | Y | | | | Y | Y | Ya | γb | | | Y |
| esta blis h | | | | | Y | | | | | | |
| spli t | | Fc | Y | | | | | | Ес | Y | |
| rest ore - full | Y | | | | Y | Υ a | ΥÞ | γa | | | Y |

Table 20. BCV control actions and applicable states (continued)

| Contr ol Opera tion | Never Established | Sync in prog | Syncronized | SyncInProg | Split | Split no incremental | Split before sync | Split before restore | Restore in prog | Restored | Invalid |
|------------------------------|-------------------|--------------|-------------|------------|-------|----------------------|-------------------|----------------------|-----------------|----------|---------|
| rest ore | | | | | Y | | | | | | |
| atta ch | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| deta ch | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| canc el | | | | | Y | | Y | Y | | | |

a. The BVC must be specified or you must use the $\ensuremath{\mathsf{-exact}}$ or $\ensuremath{\mathsf{-force}}$ option.

b. The BCV must be specified or you must use both the -force and -symforce options.

c. The F denotes that you must use the **-symforce** option.

Command options with device groups

symmir -g control arguments and possible options on page 148 lists the symmir control operations and the possible options to use when targeting a specified device group.

Table 21. symmir -g control arguments and possible options

| Options | Argument action | | | | | | | | | | |
|---------------------|--------------------|-----------|-------|------------------|---------|--------|--------|--------|--|--|--|
| | establish -full | establish | split | restore -full | restore | attach | detach | cancel | | | |
| -bcv | Y | Y | Y | Y | Y | Y | Y | Y | | | |
| - both_sid es | Y | Y | | | | | | | | | |
| -bypass | | | Y | Y | Y | | | | | | |
| -c, -i | Y | Y | Y | Y | Y | Y | Y | Y | | | |
| - concurre nt | Y | Y | | | | | | | | | |
| - consiste nt | | | Y | | | | | | | | |
| -diff | | | Y | | | | | | | | |
| -exact | Y | | | Y | | | | | | | |

| Options | Argument action | | | | | | | | | | |
|--|--------------------|-----------|-------|------------------|---------|--------|--------|--------|--|--|--|
| | establish -full | establish | split | restore -full | restore | attach | detach | cancel | | | |
| -force, - | Y | Y | Y | Y | Y | | | Y | | | |
| symforce | | | | | | | | | | | |
| -hop2 | Y | Y | Y | Y | Y | Y | Y | Y | | | |
| - noprompt | Y | Y | Y | Y | Y | Y | Y | Y | | | |
| - not_read Y | | | Y | Y | Y | | | | | | |
| -opt | Υ | | | | | | | | | | |
| - preactio n, - postacti on | Y | Y | Y | Y | Y | | | | | | |
| - preserve tgtlocks , - lockid | Υ | Υ | Y | Y | Y | | | | | | |
| - protbcve st | Y | Y | | | | | | | | | |

Table 22. symmir -g view arguments and possible options

() NOTE:

The base tasks performed with symbox such as list, associate, and disassociate locally or remotely attached BCV devices, are described at the beginning of this chapter.

Command options with composite groups

Options to the symmir -cg command line arguments provide more action flexibility to control BCV pairs when you are operating on device(s) of a specified composite group. symmir -cg control arguments and possible options on page 151 lists the **symmir** control operations and the possible options to use when targeting a specified composite group.

Table 23. symmir -cg control arguments and possible options

| Options | Argument action | | | | | | | | | | |
|--|--------------------|-----------|-------|------------------|---------|--------|--------|--------|--|--|--|
| | establish -full | establish | split | restore -full | restore | attach | detach | cancel | | | |
| -bcv | Y | Y | Y | Y | Y | Y | Y | Y | | | |
| - both_sid es | Y | Y | | | | | | | | | |
| -bypass | | | Y | Y | Y | - | | | | | |
| -c, -i | Y | Y | Y | Y | Y | Y | Y | Y | | | |
| - concurre nt | Y | Y | | | | | | | | | |
| - consiste nt, - both_sid es | | | Y | | | | | | | | |
| -diff | | | Y | | | | | | | | |
| -exact | Y | | | Y | | | | | | | |
| -force, - symforce | Y | Y | Y | Y | Y | | | | | | |

| -summary | Υ | | | | |

Table 24. symmir -cg view arguments and possible options (continued)

Command options with device files

With the symmin -file command, you can perform similar control operations on BCV device pairs defined in a device file of a specified array as you can when directing **symmin** to device groups (-g). These control operations (arguments) have similar options that allow flexibility in controlling STD/BCV pairs defined in a device file, as opposed to a device group. This command is particularly useful when operating on RDF BCV pairs in a remote array in the second-level multihop SRDF link.

symmir -file control arguments and possible options on page 153 lists the symmir control operations and the possible options to use when targeting pairs specified in a device file of a given array.

| Options | Argument a | Argument action | | | | | | | | | | | | |
|--|--------------------|-----------------|-------|------------------|---------|--------|--------|--------|--|--|--|--|--|--|
| | establish -full | establish | split | restore -full | restore | attach | detach | cancel | | | | | | |
| -bypass | | | Y | Y | Y | | | | | | | | | |
| -c, -i | Y | Y | Y | Y | Y | Y | Y | Y | | | | | | |
| - consiste nt | | | Y | | | | | | | | | | | |
| -diff | | | Y | | | | | | | | | | | |
| -force, - symforce | Y | Y | Y | Y | Y | | | Y | | | | | | |
| - noprompt | Y | Y | Y | Y | Y | Y | Y | Y | | | | | | |
| - not_read Y | | | Y | Y | Y | | | | | | | | | |
| - preactio n, - postacti on | Y | Y | Y | Y | Y | | | | | | | | | |
| - preserve tgtlocks , - lockid | Y | Y | Y | Y | Y | | | | | | | | | |

Table 25. symmir -file control arguments and possible options

Table 26. symmir -file view arguments and possible options (continued)

(i) NOTE:

The Symmetrix ID option (-sid) is required for all symmir -file commands.

Various remote multihop configurations

Various compounded remote configurations can be managed by your host using both the TimeFinder and SRDF components of SYMCLI.

As Control operations on multihop SRDF configurations on page 157 shows, you can have multiple sites (for example, remote sites C, E, F, and H) on SRDF links to remotely mirror a local array at site A. Remote site F, functioning as a remote mirror to the standard devices at site A, is most typical. You then can have a third site on an SRDF link (remote site H) to remotely mirror just the BCV devices in the array at site A.

You can also multihop to a second level SRDF where Remote site G functions as a remote mirror to the standard devices of site A and Remote site I remotely mirrors Site A's BCV.

In addition, you can also create a cascaded SRDF configuration, where tertiary site B functions as a remote partner to the R21 device at Site C, which is the remote partner of the local RDF standard device at Site A; and tertiary site D functions as a remote partner to the R21 device at Site E, which is the remote partner of the local BCV device at Site A.

Command symmir manages each of the BCV pairs at any site while symrdf manages the SRDF pairs in the SRDF link.

System-wide device groups

Before you begin applying any **symmir** operations, you must be working with an existing group of RDF devices. To create a device group containing STD and BCV RDF1 devices, enter:

```
symdg create prod -type RDF1
symdg -g prod add dev 0001 -sid 0001 DEV001
symbcv -g prod associate dev 000A BCV001
symbcv -g prod associate dev 000C -rdf RBCV001
symbcv -g prod associate dev 0009 -bcv -rdf BRBCV001
symbcv -g prod associate dev 0004 -rrdf RRBCV001
symbcv -g prod associate dev 0004 -hop2 2BCV001
```

At this point, all these devices must be established with the symmir and symrdf commands.

Commands to various multihop devices and links

This section describes the command application of targeting the various devices and links in complex multihop SRDF environments.

The following sequence of commands steps through some basic control operations that touch every device and RDF link in a complex multihop configuration. The following numbering of commands directly associates with the bubble numbers shown in the Control operations on multihop SRDF configurations on page 157.

| 1 | symrdf -g <> establish | Creates the standard-associated hop 1 copy. |
|----|---------------------------------------|--|
| 2 | symmir -g <> split -rdf | Splits the standard-associated hop 1 BCV device pair. |
| 3 | symrdf -g <> establish -rbcv | Creates the standard-associated hop 2 copy. |
| 4 | symrdf -g <> restore -rbcv | Restores the standard-associated hop 1 BCV with the hop 2 copy. |
| 5 | symmir -g <> restore -rdf | Restores the standard-associated hop 1 copy with the hop 1 BCV. |
| 6 | symrdf -g <> restore | Restores the standard device with the hop 1 copy. |
| 7 | symmir -g <> split | Splits the standard/BCV pair. |
| 8 | symrdf -g <> establish -bcv | Creates the BCV-associated hop 1 remote copy. |
| 9 | symmir -g <> split -rdf -bcv | Splits the BCV-associated hop 1 device pair. |
| 10 | symrdf -g <> establish -brbcv | Creates the BCV-associated hop 2 copy. |
| 11 | symrdf -g <> restore -brbcv | Restores the BCV-associated hop 1 BCV with the hop 2 copy. |
| 12 | symmir -g <> restore -rdf - bcv | Restores the BCV-associated hop 1 copy with the hop 1 BCV. |
| 13 | symrdf -g <> restore -bcv | Restores the BCV device with the hop 1 copy. |
| 14 | symmir -g <> restore | Restores the standard device with the BCV copy. |
| 15 | symmir -file <> -sid 044 establish | Creates the BCV-associated with the remote partner of the BRBCV (file only). |
| 16 | symmir -file <> -sid 044 split | Splits the BCV-associated with the remote partner of the BRBCV (file only). |
| 17 | symrdf -g <> establish | Creates the standard-associated hop 1 copy. |
| 18 | symrdf -g <> establish -hop2 | Creates the standard-associated hop 2 copy. |

| 19 | symmir -g <> establish -hop2 | Creates the BCV-associated hop 2 BCV copy. |
|----|---------------------------------------|---|
| 20 | symmir -g <> split -hop2 | Splits the BCV-associated hop 2 device pair. |
| 21 | symrdf -g <> restore -hop2 | Restores the standard with the hop 2 copy. |
| 22 | symrdf -g <> restore | Restores the standard device with the hop 1 copy. |
| 23 | symrdf -g <> establish -bcv | Creates the BCV-associated hop 1 remote copy. |
| 24 | symrdf -g <> establish -bcv - hop2 | Creates the BCV-associated hop 2 copy. |
| 25 | symrdf -g <> restore -bcv - hop2 | Restores the BCV-associated hop 2 copy. |
| 26 | symrdf -g <> restore -bcv | Restores the BCV device with the hop 1 copy. |

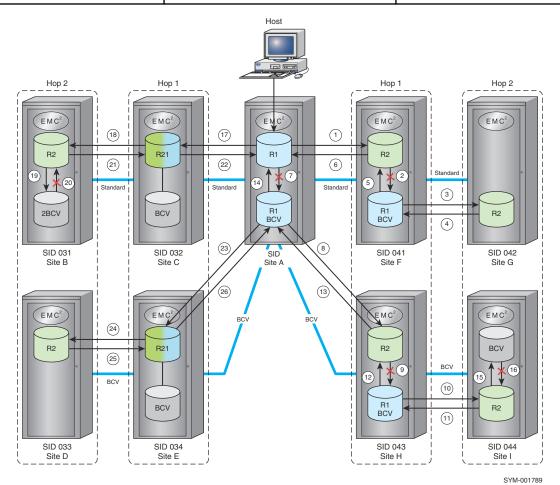

Figure 50. Control operations on multihop SRDF configurations

Second-level controls for multihop SRDF environments

As previously described, second-level multihop control operations were accomplished using the device file (-file) option for managing RDF BCV device pairs. You can use the **symmir** command for device groups (-g) for BCV control capability in second-level multihop SRDF environments.

The remote RDF BCV (RRBCV) devices must have been previously associated with the device group using the symbox -rrdf command. Compounded remote configuration on page 102 contains specific information about how to associate second-level multihop BCVs with a device group.

Once the RRBCV devices have been associated with the device group, you can use the **symmir** command with the -rrbcv option to perform control operations on the remote mirror of the remote BCV to become established, split, or restored from its BCV. Other second-level multihop BCV control operations available with the **symmir** command include query, verify, attach, detach, and cancel.

Remote optimizing option

The remote optimize (-opt_rag) option only applies to the full Establish operation in a remote array that optimizes the disk I/O on the standard/BCV pair selection to achieve a high copy speed between them. (Basically, the device pair selection attempts to pair devices that are not on the same disk adapter to distribute I/O.) This option overrides all current pairing relationships.

(i) NOTE:

This option is only applicable for remote array optimization targeting composite groups (-cg).

The command line must include the -rdf option, as follows:

symmir -cg CgName -full establish -rdf -opt_rag

Using the -remote option on multihop split actions

This section describes the command application of targeting the various devices and links with the *-remote* option in complex multihop SRDF environments.

The following sequence of commands steps through some basic control operations that touch every device and RDF link in a complex multihop configuration. The following numbering of commands directly associates with the callouts shown in the The -remote option on multihop configurations on page 159.

| 1 | symrdf -g <> establish | Creates the standard-associated hop 1 copy. |
|---|---|--|
| 2 | symmir -g <> split -rdf - remote | Splits the standard-associated hop 1 BCV device pair and creates a standard- associated hop 2 copy of the hop 1 BCV. |
| 3 | symmir -g <> split -remote | Splits the standard/BCV pair and creates a BCV-associated hop 1 copy of the local BCV. |
| 4 | symmir -g <> split -rdf -bcv -remote | Splits the BCV-associated hop 1 BCV device pair and creates a BCV- associated hop 2 copy of the hop 1 BCV. |
| 5 | symmir -g <> split -rrbcv | Splits the BCV-associated hop 2 BCV device pair. You cannot use the - remote option here. |

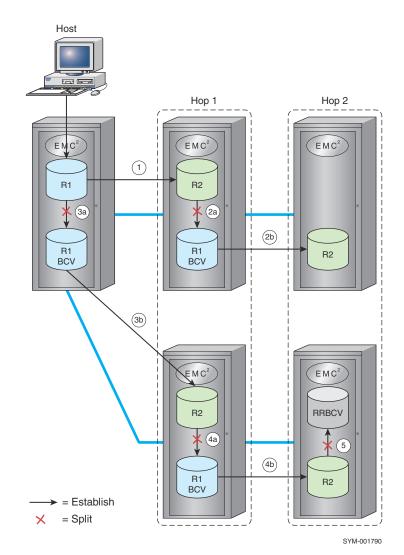

Figure 51. The -remote option on multihop configurations

TimeFinder State Rules Reference

This appendix helps you determine if the TimeFinder operation you want to complete is supported for devices in a particular pair state.

Topics:

- Using the tables for Clone, VP Snap, Snap, and Mirror
- TimeFinder/Clone operations
- VP Snap operations
- TimeFinder/Snap operations
- TimeFinder/Mirror operations

Using the tables for Clone, VP Snap, Snap, and Mirror

To determine which tables to view for a particular configuration:

- Go to the appropriate section for the operation and look at the basic operations table. For example, to perform a TimeFinder/ Clone operation, go to TimeFinder/Clone operations on page 161 and look at Basic TimeFinder/Clone operations on page 161 If the operation is supported on the device in its current pair state, go to the next step.
- 2. If the device is part of a concurrent copy operation, look at the appropriate table in the concurrent operations section. A concurrent copy operation occurs when multiple copies are made from the same source. These copies can be any combination of TimeFinder/Clone, TimeFinder/Mirror, and TimeFinder/Snap.

The following image shows a concurrent copy operation.

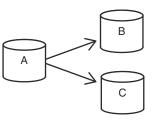

Figure 52. Concurrent copy operation

For example, to complete a TimeFinder/Clone operation on a device that is part of a concurrent copy operation in which both a clone and a snap are made from the same source device, look at Concurrent TimeFinder/Clone operations: Clone and Snap on page 166 If the operation is supported on the device in its current pair state, go to the next step.

3. If the device is part of a cascaded copy operation, look at the appropriate table in the cascaded operations section. A cascaded copy operation occurs when a device is both the source of a copy and the target of a copy, such that the devices are in the relationship of A -> B -> C. Examples of cascaded operations include Clone off Clone, Snap off Clone, and Snap off BCV.

The following image shows a cascaded copy operation.

Figure 53. Cascaded copy operation

For cascaded operations, which hop in the cascade is required. For example, when the device is part of a Snap off Clone operation in which a device (B) is the target of a clone ($A \rightarrow B$) and the source of a snap ($B \rightarrow C$).

The following image shows this example.

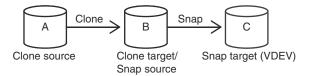

Figure 54. Cascaded copy example (Snap off Clone)

The TimeFinder/Clone hop of the cascade is described in Snap off Clone operations: Source - Target on page 173 of the TimeFinder/Clone Operations section.

The TimeFinder/Snap hop of the cascade, is described in Snap off Clone operations: B - VDEV on page 186 of the TimeFinder/Snap Operations section.

If the operation is listed as supported in each of the appropriate tables, then that operation is supported on the device.

TimeFinder/Clone operations

This section describes the TimeFinder/Clone control operations that are allowed for devices in various pair states.

Basic TimeFinder/Clone operations

The following image shows the relationship between devices for a basic TimeFinder/Clone operation.

Figure 55. Basic TimeFinder/Clone device relationship

In the following table:

- Pair state refers to the current state of the source-target pair.
- Operation refers to the intended control operation.
- Y indicates that the operation is allowable for that state.

Table 27. Basic TimeFinder/Clone operations

| Time Finde | TimeF | TimeFinder/Clone Source -> Target Pair state: | | | | | | | | | | | | | |
|--|------------|---|---------|-----------|---------|------------------|--------|---------------|----------------|-------|-----------------|----------|------------------------|---------|--------|

a. Transient state.b. Session must be differential.

c. Requires Enginuity 5876.163.105 and higher.

- d. If not already set to this mode.
- e. Cannot be differential.
- f. Requires -symmforce (not recommended).
- g Target data will be incomplete.
- h. Source data will be incomplete.

Concurrent TimeFinder/Clone operations

A concurrent copy occurs when a source device is copied to multiple different targets. These copy operations can be any combination of TimeFinder/Clone, TimeFinder Snap, and TimeFinder/Mirror copies.

Concurrent TimeFinder/Clone

The following image shows the relationship between devices for a TimeFinder/Clone pairing of a source device with two targets.

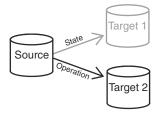

Figure 56. Concurrent TimeFinder/Clone device relationships

() NOTE:

The positions of Target 1 and Target 2 are interchangeable in the illustration above.

In the following table:

- Pair state refers to the current state of the Source-Target 1 pair.
- *Operation* refers to the intended control operation on the Source-Target 2 pair.
- Y indicates that the operation is allowable for that state.

Table 28. Concurrent TimeFinder/Clone operations

| Time | TimeFi | inder/C | lone So | urce -> | Target | 1 Pair s | state: | | | | | | | | |
|---|------------|----------------|---------|----------------|---------|------------------|--------|---------------|----------------|-------|-----------------|----------|------------------------|---------|--------|

Table 30. Concurrent TimeFinder/Clone operations: Clone and Snap

a. Transient state.

b. Session must be differential.

c. Requires Enginuity 5876.163.105 and higher.

d. If not already set to this mode.

e. Cannot be differential.

Cascaded TimeFinder/Clone operations

A cascaded copy operation occurs when a device is both the source of a copy and the target of a copy, such that the devices are in the relationship of A -> B -> C.

Cascaded TimeFinder/Clone (Clone off Clone): A - B

The following image shows the relationship between devices for a Clone off Clone operation in which source device A is paired with target device B and an additional session uses device B as a source paired with target device C.

Figure 59. Clone off Clone device relationship: A -> B

Limitations

- Cascading with thin devices is supported on Enginuity 5876.
- Mixed thick and thin devices are not supported. All devices in a cascaded session must be thick or thin.
- Cascaded sessions cannot exceed two hops.

In the following table:

- Pair state refers to the current state of the B-C pair.
- Operation refers to the intended control operation on the A-B pair.
- Y indicates that the operation is allowable for that state.

Table 31. Clone off Clone operations: A - B

| Time | TimeFi | inder/C | lone B | -> C Pai | ir state: | : | | | | | | | | | |
|---|------------|----------------|---------|-----------|-----------|------------------|--------|---------------|----------------|-------|-----------------|----------|-------------------|---------|--------|

e. If not already set to this mode.

f. Cannot be differential.

g. Requires Enginuity 5876.

Mirror off Clone: Source - STD

The following image shows the relationship between devices for a Mirror off Clone operation in which the TimeFinder/Clone source device is paired with a target device and an additional session uses that device as the STD for TimeFinder/Mirror paired with a BCV.

Figure 61. Mirror off Clone device relationship

Limitations:

- Thin BCVs are only supported for Enginuity 5876.
- Cascading with thin devices is supported on Enginuity 5876.
- Mixed thick and thin devices are not supported. All devices in a cascaded session must be thick or thin.
- Cascaded sessions cannot exceed two hops.

In the following table:

- Pair state refers to the current state of the STD-BCV pair.
- Operation refers to the intended control operation on the Source-STD pair.
- Y indicates that the operation is allowable for that state.

Table 33. Mirror off Clone operations: Source - STD

| Split | Y | | Y | | Υa | Y | | Y | Υa | |
| Terminat e | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |

a. Native TimeFinder/Mirror only.

- b. Session must be differential.
- c. If not already set to this mode.
- d. Cannot be differential.
- e. Requires Enginuity 5876 .

Clone off Mirror: BCV - Target

The following image show the relationship between devices for a Clone off Mirror operation in which the TimeFinder/Mirror STD device is paired with a BCV device and an additional session uses that device as the source for TimeFinder/Clone paired with a target device.

Figure 62. Clone off Mirror device relationship

Limitations:

- Thin BCVs are only supported for Enginuity 5876.
- Cascading with thin devices is supported on Enginuity 5876.
- Mixed thick and thin devices are not supported. All devices in a cascaded session must be thick or thin.
- Cascaded sessions cannot exceed two hops.

In the following table:

- Pair state refers to the current state of the STD-BCV pair.
- Operation refers to the intended control operation on the BCV-Target pair.
- Y indicates that the operation is allowable for that state.

Table 34. Clone off Mirror operations: BCV - Target

| | TimeFinder/Mirror STD -> BCV Pair state: | | | | | | | | | | | |
|--|--|------------|-------------|-----------------|----------|----------------------|-------------------|-------|-------------------|----------------------|--|--|

| Split | Y | | | | | Y | | Y | | |
| Terminat e | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |

a. Session must be differential.

b. If not already set to this mode.

c. Cannot be differential.

d. Requires Enginuity 5876.

Snap off Clone: Source - Target

The following image shows the relationship between devices for a Snap off Clone operation in which the TimeFinder/Clone source device is paired with a target device and an additional session uses the target device as the source for TimeFinder/Snap paired with a VDEV.

Figure 63. Snap off Clone device relationship

() NOTE:

The TimeFinder/Snap session is not considered to be a hop and does not contribute to the two hop maximum.

- Pair state refers to the current state of the Target-VDEV pair.
- Operation refers to the intended control operation on the Source-Target pair.

• Y indicates that the operation is allowable for that state.

Table 35. Snap off Clone operations: Source - Target

| TimeFin | TimeFind | ler/Snap T | Target -> ' | VDEV Pair | state: | | | | | | |
|---|------------|---------------------|-------------|-----------|--------|---------------|-----------------|----------|-------------------|---------|--------|
| der/ Clone Source -> Target Operati on: | No session | Create in prog • | Created | Recreated | Copied | Copy on write | Restore in prog | Restored | Terminate in prog | Invalid | Failed |
| Create | Y | | | | | | | | | | |

| Set Mode Copy ^f | Y | | | | | | | | | | |
| Set Mode Nocopy ^{f, g} | Y | | | | | | | | | | |
| Set Mode Precopy f | Y | | | | | | | | | | |
| Full Restore ^b | Y | | | | | | | | | | |
| Increme ntal Restore b | Y | | | | | | | Y | | | |
| Split | Y | | | | Y | Y | | | | | |
| Terminat e | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |

a. Transient state.

b. Session must be differential.

c. If the TimeFinder/Clone target has a TimeFinder/Snap session in any state, recreate is allowed only with precopy mode.

d. Requires Enginuity 5876.163.105 and higher.

- e. If the TimeFinder/Clone target has a TimeFinder/Snap session in any state, activate is allowed only after the precopy operation has completed one cycle. This can be verified with a symclone query.
- $\ensuremath{\scriptscriptstyle \mathrm{f.}}$ If not already set to this mode.
- g. Cannot be differential.

VP Snap operations

VP Snap operations have rules not covered in the previous tables.

Basic VP Snap operations

The following image shows the relationship between devices for a basic VP Snap operation.

Figure 64. Basic VP Snap device relationship

In the following table:

- Pair state refers to the current state of the Source-Target pair.
- Operation refers to the intended control operation on the Source-Target pair.
- Y indicates that the operation is allowable for that state.

Table 36. Basic VP Snap operations

| | VP Snap Source -> Target Pair state: | | | | | | | | | | | |
|--|--------------------------------------|---------|-----------|--------|---------------|-----------------|----------|---------|--------|--|--|--|
| VP Snap Source -> Target Operation : | No session | Created | Recreated | Copied | Copy on write | Restore in prog | Restored | Invalid | Failed | | | |

TimeFinder/Snap operations

This section describes the TimeFinder/Snap control operations that are allowed for devices in various pair states.

Basic TimeFinder/Snap Operations

The following image shows the relationship between devices for a basic TimeFinder/Snap operation.

Figure 70. Basic snap device relationship

- Pair state refers to the current state of the Source-VDEV pair.
- Operation refers to the intended control operation.
- Y indicates that the operation is allowable for that state.

Table 42. Basic TimeFinder/Snap operations

| TimeFin | TimeFinder/Snap Source -> VDEV Pair state: | | | | | | | | | | | |
|--|--|---------------------|---------|-----------|--------|---------------|-----------------|----------|-------------------|---------|--------|--|
| der/ Snap Source -> VDEV Operati on: | No session | Create in prog • | Created | Recreated | Copied | Copy on write | Restore in prog | Restored | Terminate in prog | Invalid | Failed | |
| Create | Y | | | | | | | | | | | |
| Create - duplicate | | | | | Y | Y | | | | | | |
| Duplicat e | | | | | Y | Y | | | | | | |
| Recreat e ^b | | - | - | | Y | Y | | | | | | |
| Activate | | | Y | Y | | | | | | | | |
| Activate - duplicate | | | Y | | | | | | | | | |
| Full Restore c | | | | | Y | Y | | | | | | |
| Increme ntal Restore | | | | | Y | Y | | | | | | |
| Terminat e | | Y | Y | Y | Y | Y | Υd | Y | Y | Y | Y | |

a. Transient state.

b. Requires Enginuity 5876.

c. The restore to a third device must not be related to any session associated with the TimeFinder/Snap source device. The third device must be the same thick or thin configuration as the TimeFinder/Snap source device.

d. Requires -symforce (not recommended).

Concurrent TimeFinder/Snap operations

A concurrent copy occurs when a source device is copied to multiple different targets. These copy operations can be any combination of TimeFinder/Clone, TimeFinder Snap, and TimeFinder/Mirror copies.

Concurrent TimeFinder/Snap

The following image shows the relationship between devices for a TimeFinder/Clone pairing of a source device with two targets.

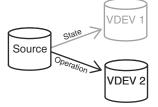

Figure 71. Concurrent TimeFinder/Snap device relationships

() NOTE:

The positions of VDEV 1 and VDEV 2 are interchangeable in the illustration above.

In the following table:

- Pair state refers to the current state of the Source-VDEV 1pair.
- Operation refers to the intended control operation on the Source-VDEV 2 pair.
- Y indicates that the operation is allowable for that state.

Table 43. Concurrent TimeFinder/Snap operations

| TimeFin | TimeFind | ler/Snap S | Source -> | VDEV 1 Pa | ir state: | | | | | | |
|--|------------|----------------|-----------|-----------|-----------|---------------|-----------------|----------|-------------------|---------|--------|
| der/ Snap Source -> VDEV 2 Operati on: | No session | Create in prog | Created | Recreated | Copied | Copy on write | Restore in prog | Restored | Terminate in prog | Invalid | Failed |
| Create | Y | | Y | Y | Y | Y | | | | | |
| Create - duplicate | Y | | Y | Y | Y | Y | | Y | | | |
| Duplicat e | Y | | Y | Y | Y | Y | | Y | | | |
| Recreat e ^b | Y | | Y | Y | Y | Y | | | | | |
| Activate | Y | | Y | Y | Y | Y | | | | | |

| Full Restore d | Y | | Y | Y | Y | Y | | | | | |
| Increme ntal Restore | Y | | | | Y | Y | | | | | |
| Terminat e | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |

a. Transient state.

b. Requires Enginuity 5876.

c. Requires Solutions Enabler version 7.4 and higher.

d. The restore to a third device must not be related to any session associated with the TimeFinder/Snap source device. The third device must be the same thick or thin configuration as the TimeFinder/Snap source device.

Concurrent TimeFinder/Snap: Snap and Mirror

The following image shows the relationship between devices for a concurrent pairing of a source device with a TimeFinder/Snap VDEV and a TimeFinder/Mirror BCV.

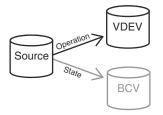

Figure 72. Concurrent TimeFinder/Snap device relationships: Snap and Mirror

() NOTE:

The positions of VDEV and BCV are interchangeable in the illustration above.

In the following table:

- Pair state refers to the current state of the STD-BCV pair.
- Operation refers to the intended control operation on the Source-VDEV pair.
- Y indicates that the operation is allowable for that state.

Table 44. Concurrent TimeFinder/Snap operations: Snap and Mirror

| | TimeFind | er/Mirror S | STD -> BCV | ' Pair state | : | | | | | |

| Termi nate | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |

Table 45. Concurrent TimeFinder/Snap operations: Snap and Clone (continued)

a. Transient state

b. Requires Enginuity 5876.

c. Requires Solutions Enabler version 7.4 and higher.

d. The restore to a third device must not be related to any session associated with the TimeFinder/Snap source device. The third device must be the same thick or thin configuration as the TimeFinder/Snap source device.

Cascaded TimeFinder/Snap operations

A cascaded copy operation occurs when a device is both the source of a copy and the target of a copy, such that the devices are in the relationship of A -> B -> C.

Snap off Mirror: BCV - VDEV

The following image shows the relationship between devices for a Snap off Mirror operation in which the TimeFinder/Mirror STD device is paired with a BCV device and an additional session uses that device as the source for TimeFinder/Snap paired with a VDEV.

Figure 74. Snap off Mirror device relationship

- Cascading with thin devices is supported on Enginuity 5876.
- Mixed thick and thin devices are not supported. All devices in a cascaded session must be thick or thin.
- Cascaded sessions cannot exceed two hops.

 The TimeFinder/Snap session is not considered to be a hop and does not contribute to the two hop maximum. Therefore, the STD -> BCV pairing could be preceded by a clone session such that the final cascade is Clone Source -> STD -> BCV -> VDEV.

In the following table:

- Pair state refers to the current state of the STD-BCV pair.
- Operation refers to the intended control operation on the BCV-VDEV pair.
- Y indicates that the operation is allowable for that state.

Table 46. Snap off Mirror operations: BCV - VDEV

| | TimeFinde | er Mirror S | TD -> BCV | Pair State | : | | | | | |
|---|-------------------|-------------|-------------|-----------------|----------|----------------------|---------------|-------|-------------------|----------------------|

| Recreate ª | Y | | | | | Y | | Y | | |
| Activate | Y | | | | | Y | | Y | | |
| Activate - duplicate | Y | | | | | Y | | Y | | |
| Full Establish ^b | Y | | | | | Y | | Y | | |
| Incremen tal Establish b | Y | | | | | Y | | Y | | |
| Full Restore ^c | Y | | | | | Y | | Y | | |
| Incremen tal Restore ^a | Y | | | | | Y | | Y | | |
| Terminat e | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |

a. Requires Enginuity 5876.

b. Requires Solutions Enabler version 7.4 and higher.

c. The restore to a third device must not be related to any session associated with the TimeFinder/Snap source device. The third device must be the same thick or thin configuration as the TimeFinder/Snap source device.

Snap off Clone: B - VDEV

The following image shows the relationship between devices for a Snap off Clone operation in which the TimeFinder/Clone source device is paired with a target device and an additional session uses the target device as the source for TimeFinder/Snap paired with a VDEV.

Figure 75. Snap off Clone device relationship

Limitations:

- Cascading with thin devices is supported on Enginuity 5876.
- Mixed thick and thin devices are not supported. All devices in a cascaded session must be thick or thin.
- Cascaded sessions cannot exceed two hops.
- The TimeFinder/Snap session is not considered to be a hop and does not contribute to the two hop maximum. Therefore, the STD -> BCV pairing could be preceded by a clone session such that the final cascade is Clone Source -> STD -> BCV -> VDEV.

In the following table:

- Pair state refers to the current state of the A-B pair.
- Operation refers to the intended control operation on the B-VDEV pair.
- Y indicates that the operation is allowable for that state.

Table 47. Snap off Clone operations: B - VDEV

| Time | TimeFi | inder/C | lone A · | -> B Pai | r state: | | | | | | | | | | |

| Termi nate | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |

a. Transient State

b. Requires Enginuity 5876.

c. Requires Solutions Enabler version 7.5 and higher and Enginuity 5876.

- d. Requires Solutions Enabler version 7.4 and higher.
- e. The restore to a third device must not be related to any session associated with the TimeFinder/Snap source device. The third device must be the same thick or thin configuration as the TimeFinder/Snap source device.

TimeFinder/Mirror operations

This section describes the TimeFinder/Mirror control operations that are allowed for devices in various pair states.

Basic TimeFinder/Mirror operations

The following image shows the relationship between devices for a basic TimeFinder/Mirror operation.

Figure 76. Basic TimeFinder/Mirror device relationship

Limitations:

- With Enginuity 5876, all TimeFinder/Mirror operations are done with TimeFinder/Clone Emulation. With Enginuity 5773, the default mode is native TimeFinder/Mirror, and TimeFinder/Clone Emulation is a selectable option.
- RAID5 and RAID6 BCVs automatically use TimeFinder/Clone Emulation.
- Thin BCVs are supported with Enginuity 5876.

In the following table:

- Pair state refers to the current state of the STD-BCV pair
- Operation refers to the intended control operation.
- Y indicates that the operation is allowable for that state.

Table 48. Basic TimeFinder/Mirror operations

| | TimeFinde | er/Mirror S | TD -> BCV | Pair state | : | | | | | |
|---|-------------------|------------------|-------------|-----------------|----------|----------------------|-------------------|-------|-------------------|----------------------|
| TimeFin der Mirror STD -> BCV Operatio n: | Never Established | Sync in prog | Syncronized | Restore in prog | Restored | Split no incremental | Split in progress | Split | Split before sync | Split before restore |
| Full Establish | Y | | | | | Y | | Y | Y | |
| Incremen tal Establish | | | | | | | | Y | | |
| Split | | Y ^{a,b} | Y | Ya,c, d | Y | | | | | |
| Full Restore | Y | | | | | Y | | Y | | Y |
| Incremen tal Restore | | | | | | | | Y | | |
| Cancel | | | | | | | | Y | | |

a. Requires -symmforce (not recommended)

b. With native TimeFinder/Mirror, this results in the Split Before Sync state, which indicates that the BCV data is not complete. With TimeFinder/Clone Emulation mode, this results in the Split state, which indicates that the BCV data is complete.

c. Results in the Split Before Restore state, which indicates that the STD data is not complete.

d. Native TimeFinder/Mirror only.

Concurrent TimeFinder/Mirror operations

A concurrent copy occurs when a source device is copied to multiple different targets. These copy operations can be any combination of TimeFinder/Clone, TimeFinder/Snap, and TimeFinder/Mirror copies.

Concurrent TimeFinder/Mirror

The following image shows the relationship between devices for a TimeFinder/Mirror pairing of a STD device with two BCVs.

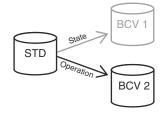

Figure 77. Concurrent TimeFinder/Mirror device relationships

(i) NOTE:

The positions of BCV 1 and BCV 2 are interchangeable in the illustration above.

Limitations:

• With Enginuity 5876, all TimeFinder/Mirror operations are done with TimeFinder/Clone Emulation. With Enginuity 5773, the default mode is native TimeFinder/Mirror, and TimeFinder/Clone Emulation is a selectable option.

- RAID5 and RAID6 BCVs automatically use TimeFinder/Clone Emulation.
- Thin BCVs are supported with Enginuity 5876.

- Pair state refers to the current state of the STD-BCV 1 pair
- Operation refers to the intended control operation on the STD-BCV 2 pair
- Y indicates that the operation is allowable for that state.

Table 49. Concurrent TimeFinder/Mirror operations

| | TimeFinde | er/Mirror S | TD -> BCV | 1 Pair stat | e: | | | | | |
|--|-------------------|--------------|-------------|-----------------|----------|----------------------|-------------------|-------|-------------------|----------------------|

a. Transient state.

b. Native TimeFinder/Mirror only.

Cascaded TimeFinder/Clone operations

A cascaded copy operation occurs when a device is both the source of a copy and the target of a copy, such that the devices are in the relationship of A -> B -> C.

Clone off Mirror: STD - BCV

The following image shows the relationship between devices for a Clone off Mirror operation in which the TimeFinder/Mirror STD device is paired with a BCV and an additional session uses that device as the source for TimeFinder/Clone paired with a target device.

Figure 80. Clone off Mirror device relationship

- With Enginuity 5876, all TimeFinder/Mirror operations are done with TimeFinder/Clone Emulation. With Enginuity 5773, the default mode is native TimeFinder/Mirror, and TimeFinder/Clone Emulation is a selectable option.
- RAID5 and RAID6 BCVs automatically use TimeFinder/Clone Emulation.

- Thin BCVs are supported with Enginuity 5876.
- Mixed thick and thin devices are not supported. All devices in a cascaded session must be thick or thin.
- Cascaded sessions cannot exceed two hops.

- Pair state refers to the current state of the BCV-Target pair.
- Operation refers to the intended control operation on the STD-BCV pair.
- Y indicates that the operation is allowable for that state.

Table 52. Clone off Mirror operations: STD - BCV

| Time | TimeFi | inder/C | lone BC | :V -> Ta | rget Pa | nir state |): | | | | | | | | |

SRDF State Rules Reference

This appendix describes the applicable SRDF pair states that rule the TimeFinder SnapVX, TimeFinder/Clone, and TimeFinder/Snap copy session operations.

Topics:

- SRDF pair states
- State rules for TimeFinder/Clone operations
- State rules for TimeFinder/Snap operations

SRDF pair states

Certain TimeFinder copy operations are not allowed within arrays employing SRDF for remote mirroring as these operations can conflict with one another. The availability of some actions depends on the current state of SRDF pairs. Refer to your product guide for details about supported features.

The following table provides a description the various SRDF pair states.

Table 55. SRDF pair states

| State | Description |
|--------------|--|
| ActiveActive | The R1 and the R2 are currently in the default SRDF/Metro configuration which uses a Witness array: There are no invalid tracks between the two pairs. The R1 and the R2 are Ready (RW) to the hosts. |
| ActiveBias | The R1 and the R2 are currently in an SRDF/Metro configuration using bias: The user could have specified "use bias" during the establish/restore action or the Witness array is not available. There are no invalid tracks between the two pairs. The R1 and the R2 are Ready (RW) to the hosts. |
| Consistent | The R2 mirrors of SRDF/A devices are in a Consistent state. Consistent state signifies the normal state of operation for device pairs operating in asynchronous mode. |
| Failed Over | The R1 is currently Not Ready or write disabled and operations have been failed over to the R2. |
| Invalid | The default state when no other SRDF state applies. The combination of R1, R2, and SRDF link states and statuses do not match any other pair state. This state may occur if there is a problem at the disk director level. |
| Mixed | A composite device group SRDF pair state. There exists different SRDF pair states within a device group. |
| Partitioned | Solutions Enabler is currently unable to communicate through the corresponding SRDF path to the remote array. Partitioned may apply to devices within an RA group. For example, if Solutions Enabler is unable to communicate to a remote array via an RA group, devices in that RA group will be marked as being in the Partitioned state. |

Table 55. SRDF pair states (continued)

| State | Description |
|---------------|---|
| R1 Updated | The R1 is currently Not Ready or write disabled to the host, there are no local invalid tracks on the R1 side, and the link is Ready or write disabled. |
| R1 UpdInProg | The R1 is currently Not Ready or write disabled to the host, there are invalid local (R1) tracks on the source side, and the link is Ready or write disabled. |
| Split | The R1 and the R2 are currently Ready to their hosts, but the link is Not Ready or write disabled. |
| Suspended | The SRDF links have been suspended and are Not Ready or write disabled. If the R1 is Ready while the links are suspended, any I/O will accumulate as invalid tracks owed to the R2. |
| Synchronized | The R1 and the R2 are currently in a Synchronized state. The same content exists on the R2 as the R1. There are no invalid tracks between the two pairs. |
| SyncInProg | A synchronization is currently in progress between the R1 and the R2. There are existing invalid tracks between the two pairs and the logical link between both sides of an SRDF pair is up. |
| Transmit Idle | The SRDF/A session cannot push data in the transmit cycle across the link because the link is down. |

State rules for TimeFinder/Clone operations

This section identifies the symclone copy actions that are available for use within each of the SRDF pair states.

This section refers to the copy source and the copy target. It is important to note that "source" and "target" refer to the direction of the data flow. In this context, these terms do not refer to the TimeFinder/Clone device pair relationship.

The following image shows an establish operation for which the R1 device is the source of the data for the clone copy operation. In other words, the TimeFinder/Clone source device is the source for the clone copy.

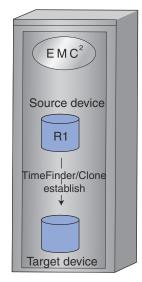

Figure 83. R1 device as TimeFinder/Clone copy source.

The following image shows a restore operation for which the R1 device is the target of the data for the clone copy operation. In other words, for a restore, the TimeFinder/Clone source device is the target of the clone copy.

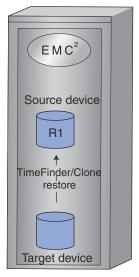

Figure 84. R1 device as TimeFinder/Clone copy target.

TF/Clone operations R1 source

Table 56. TF/Clone operations allowed when R1 is source of clone copy data

| | SRDF | State | : | | | | | | | | | | | |
|-----------------------------|--------------|-------------|-------|-----------|-------------|--------------|--------------|------------|--------------|---------|------------|--------------|--------------|------------|
| Clone Control Operation: | Sync in prog | Syncronized | Split | Suspended | Failed over | Partitioned1 | Partitioned2 | R1 updated | R1 updinprog | Invalid | Consistent | Transmitldle | ActiveActive | ActiveBias |
| Create/recreate | Y | Y | Y | Y | Y | Y | | Y | | | Ya | Y | Y | Y |
| Activate | Ya | Y | Y | Y | Y | Y | | Yb | Yb | | Ya | Y | Y | Y |
| Establish | Ya | Y | Y | Y | Y | Y | | Yb | Yb | | Ya | Y | Y | Y |
| Terminate | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| Restore | Ya | Y | Y | Y | | Y | | Y | Y | | Ya | Y | | |
| Split | Y | Y | Y | Y | Y | Y | Y | Y | | | Y | Y | Yc | Yc |

a. Action is not allowed if there are local R1 invalids or remote R2 invalids.

b. Action is not allowed if the -consistent option is specified.

c. Only applies for Solutions Enabler V9.0 and higher.

TF/Clone operations R1 target

Table 57. TF/Clone operations allowed when R1 is target of clone copy data

| | SRDF State: | | | | | | | | | | | | | |
|-----------------------------|--------------|-------------|-------|-----------|-------------|--------------|--------------|------------|--------------|---------|------------|--------------|--------------|------------|
| Clone Control Operation: | Sync in prog | Syncronized | Split | Suspended | Failed over | Partitioned1 | Partitioned2 | R1 updated | R1 updinprog | Invalid | Consistent | Transmitldle | ActiveActive | ActiveBias |
| Create/recreate | Ya,b,c | Yb,c | Y | Y | | Υ | | | | | Ya,b,c | Y | | |
| Activate | Ya,b,c | Yb,c | Y | Y | | Y | | | | | Ya,b,c | Y | | |

Table 57. TF/Clone operations allowed when R1 is target of clone copy data (continued)

| | SRDF State: | | | | | | | | | | | | | |
|-----------------------------|--------------|-------------|-------|-----------|-------------|--------------|--------------|------------|--------------|---------|------------|--------------|--------------|------------|
| Clone Control Operation: | Sync in prog | Syncronized | Split | Suspended | Failed over | Partitioned1 | Partitioned2 | R1 updated | R1 updinprog | Invalid | Consistent | TransmitIdle | ActiveActive | ActiveBias |
| Establish | Ya,b,c | Yb,c | Y | Y | | Y | | | | | Ya,b,c | Y | | |
| Terminate | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| Restore | Ya,b,c | Yb,c | Y | Y | | Y | | | | | Ya,b,c | Y | | |
| Split | Ya,b,c | Yb,c | Y | Y | | Y | Y | | | | Ya,b,c | Y | | |

a. Action is not allowed if there are local R1 invalids or remote R2 invalids.

b. The -force option must be applied.

c. Action is not allowed with CopyOnAccess.

TF/Clone operations R2 source

Table 58. TF/Clone operations allowed when R2 is source of clone copy data

| | SRDF | State: | | | | | | | | | | | | |
|-----------------------------|--------------|-------------|-------|-----------|-------------|--------------|--------------|------------|--------------|---------|------------|--------------|--------------|------------|
| Clone Control Operation: | Sync in prog | Syncronized | Split | Suspended | Failed over | Partitioned1 | Partitioned2 | R1 updated | R1 updinprog | Invalid | Consistent | Transmitldle | ActiveActive | ActiveBias |
| Create/recreate | Ya | Y | Ya | Ya | γa, b | Y | | Υ a,b | Υ a,b | | Υ a,b | үс | Y | Y |
| Activate | γd | Y | Y | Y | Y | Y | | Y | Y | | Y e | Ye | Y | Y |
| Establish | γa,d | Y | Υa | Υa | γa, b | Y | | Υ a,b | Υ a,b | | γa, b,e | үс,е | Y | Y |
| Terminate | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| Restore | | Y | Y | Y | Y | Y | | | | | | | | |
| Split | | Y | Y | Y | Y | Y | Y | | | | | | | |

a. If the precopy option is not applied, the action is not allowed if either of the following applies:

1. SRDF/A device-level write pacing is not activated and supported on the SRDF/A session, or

2. The SRDF pair is the R21-> R2 of a cascaded configuration and any of the following apply:

a. The R21 Symmetrix array is running an Enginuity level lower than 5876.159.102, or

b. The R2 Symmetrix array is running an Enginuity level lower than 5876, or

c. The R21 device is not pace-capable.

b. With Enginuity 5773 and lower, the precopy option (-precopy) must be applied.

 $\ensuremath{\mathsf{c}}.$ The precopy option (-precopy) must be applied for SRDF/A.

d. Action is not allowed if there are remote R1 invalids or local R2 invalids.

e. Action is not allowed if there are local R1 invalids or remote R2 invalids.

TF/Clone operations R2 target

Table 59. TF/Clone operations allowed when R2 is target of clone copy data

| | SRDF | State: | | | | | | | | | | | | |
|-----------------------------|--------------|-------------|-------|-----------|------------------|--------------|--------------|------------|--------------|---------|------------|--------------|--------------|------------|
| Clone Control Operation: | Sync in prog | Syncronized | Split | Suspended | Failed over | Partitioned1 | Partitioned2 | R1 updated | R1 updinprog | Invalid | Consistent | Transmitldle | ActiveActive | ActiveBias |
| Create/recreate | | | Υa | Ya | Y a,b | Ya | | | | | | | | |
| Activate | | | Ya | Ya | Ya,b | Ya | | | | | | | | |
| Establish | | | Ya | Ya | Ya,b | Ya | | | | | | | | |
| Terminate | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | | |
| Restore | | | Ya | Ya | Y ^{a,a} | Ya | | | | | | | | |
| Split | | | Ya | Ya | үа,а | Ya | | | | | | | | |

a. Action is not allowed if the target device is an R2 larger than the R1.

b. Action is not allowed if the R2 target device is in asynchronous mode.

State rules for TimeFinder/Snap operations

This section identifies what **symsnap** copy actions are available for use within each of the SRDF pair states.

TimeFinder/Snap operations R1 source

Table 60. TimeFinder/Snap operations allowed when R1 is source of the snap

| | SRDF State: | | | | | | | | | | | | | |
|---|--------------|-------------|-------|-----------|-------------|--------------|--------------|----------------|----------------|---------|------------|--------------|--|--|

Table 60. TimeFinder/Snap operations allowed when R1 is source of the snap (continued)

| | SRDF St | SRDF State: | | | | | | | | | | | | |
|---|--------------|-------------|-------|-----------|-------------|--------------|--------------|------------|--------------|---------|------------|--------------|--|--|
| Snap Contro I Operat ion: | Sync in prog | Syncronized | Split | Suspended | Failed over | Partitioned1 | Partitioned2 | R1 updated | R1 updinprog | Invalid | Consistent | TransmitIdle | | |
| BCV or full restore to any device | | | | | | | | | | | | | | |

a. Action is not allowed if there are local invalids on the R1 side or remote invalids owed to the R1 on the R2 side.

b. Action is not allowed if there are local R1 invalids or remote R2 invalids.

c. The force option (-force) must be applied.

TimeFinder/Snap operations R1 target

Table 61. TimeFinder/Snap operations allowed when R1 is target of the snap

| | SRDF St | tate: | | | | | | | | | | |
|--|--------------|-------------|-------|-----------|-------------|--------------|--------------|------------|--------------|---------|------------|--------------|

- a. Action is not allowed if either of the following is true:
 - 1. SRDF/A device-level write pacing is not activated and supported on the SRDF/A session, or
 - 2. The SRDF pair is the R21-> R2 of a cascaded configuration, and any of the following apply:
 - a. The R21 Symmetrix array is running an Enginuity level lower than 5876.159.102, or
 - b. The R2 Symmetrix array is running an Enginuity level 5773, or
 - c. The R21 device is not pace-capable.
- b. Action is not allowed if the SRDF pair is operating in asynchronous mode and any of the following are true:
 - 1. SRDF/A device-level write pacing is not configured for autostart on the R1 side of the SRDF/A session, or
 - 2. The SRDF pair is the R21-> R2 of a cascaded configuration and either of the following applies:
 - a. The R21 Symmetrix array is running an Enginuity level lower than 5876 Q2012 SR, or
 - b. The R2 Symmetrix array is running Enginuity level 5773.
 - **3.** The SRDF pair is not the R21-> R2 of a cascaded configuration and either the R1 or the R2 Symmetrix array is running Enginuity level 5773.
- c. Action is not allowed if there are remote invalids owed to the R2 on the R1 side or local invalids on the R2 side.
- d. Action is not allowed if the R2 target is in asynchronous mode.
- e. The force option (-force) must be applied.

TimeFinder/Snap operations R2 target

Table 63. TimeFinder/Snap operations allowed when R2 is target of the snap

| | SRDF St | ate: | | | | | | | | | | |
|---------------------------------------|--------------|-------------|-------|-----------|-------------|--------------|--------------|------------|--------------|---------|------------|--------------|
| Snap Contro I Operat ion: | Sync in prog | Syncronized | Split | Suspended | Failed over | Partitioned1 | Partitioned2 | R1 updated | R1 updinprog | Invalid | Consistent | Transmitldle |

| Snap Contro I Operat ion: | Sync in prog | Syncronized | Split | Suspended | Failed over | Partitioned1 | Partitioned2 | R1 updated | R1 updinprog | Invalid | Consistent | TransmitIdle |
| to a split BCV or full restore to any device | | | | | | | | | | | | |

ORS State Rules Reference

This appendix describes the interaction rules for TimeFinder SnapVX /snap/Clone operations with ORS rcopy states.

Topics:

• TimeFinder/Snap and TimeFinder/Clone operations

TimeFinder/Snap and TimeFinder/Clone operations

This section identifies the Snap and Clone control operations that are available in each of the rcopy pair states.

Clone source with rcopy push

The following table identifies clone operations allowed when a TimeFinder Clone source device is the control device for a rcopy PUSH session.

Table 64. TimeFinder Clone source device is control device for rcopy push session

| | rcopy state: | | | | | | | | | | | | | | | | | |
|--|--------------|----------------|---------|------------------|---------------|--------|----------------------|-----------|-------------------|--------|---------|--------------------|-----------------|----------|---------|--------------|-------------|---------|
| Clo ne Con trol Ope rati on: | None | Create in prog | Created | Copy in progress | Copy on write | Copied | Recreate in progress | Recreated | Terminate in prog | Failed | Invalid | Verify in progress | Restore in prog | Restored | Precopy | Sync in prog | Syncronized | Stopped |
| Crea te/ recr eate | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| Acti vate | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| Esta blish | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| Ter mina te | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| Rest ore | Y | | | | Ya | | | | | | | | | | | | | |
| Split | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |

a. Not supported for incremental restore on arrays running Enginuity less than 5876.

Clone source with rcopy pull

The following table identifies clone operations allowed when a TimeFinder Clone source device is the control device for a rcopy PULL session.

Table 65. TimeFinder Clone source device is control device for rcopy pull session

| | rcopy | y state |): | | | | | | | | | | | | | | | |
|--|-------|----------------|---------|------------------|---------------|--------|----------------------|-----------|-------------------|--------|---------|--------------------|-----------------|----------|---------|--------------|-------------|---------|
| Clo ne Con trol Ope rati on: | None | Create in prog | Created | Copy in progress | Copy on write | Copied | Recreate in progress | Recreated | Terminate in prog | Failed | Invalid | Verify in progress | Restore in prog | Restored | Precopy | Sync in prog | Syncronized | Stopped |
| Cre ate/ recr eate | Y | | | | | | | | | | | | | Y | | | | |
| Acti vate | Y | | | | | | | | | | | | | Y | | | | |
| Esta blish | Y | | | | | | | | | | | | | Y | | | | |
| Ter min ate | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | | Y | Y | Y | Y | Y |
| Rest ore | Y | | | | | | | | | | | | | Ya,b | | | | |
| Split | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |

a. Not supported with Donor Update.

b. Not supported for incremental restore on arrays running Enginuity less than 5876.

Clone target with rcopy push

The following table identifies clone operations allowed when a TimeFinder Clone target device is the control device for a rcopy PUSH session.

Table 66. TimeFinder Clone target device is control device for rcopy push session

| | rcopy | / state | : | | | | | | | | | | | | | | | |
|--|-------|----------------|---------|------------------|---------------|--------|----------------------|-----------|-------------------|--------|---------|--------------------|-----------------|----------|---------|--------------|-------------|---------|
| Clon e Con trol Ope rati on: | None | Create in prog | Created | Copy in progress | Copy on write | Copied | Recreate in progress | Recreated | Terminate in prog | Failed | Invalid | Verify in progress | Restore in prog | Restored | Precopy | Sync in prog | Syncronized | Stopped |
| Crea te/ recr eate | Y | | | | | Y | | | | | | | | | | | | |
| Acti vate | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| Esta blish | Y | | | | | Y | | | | | | | | | | | | |

Table 66. TimeFinder Clone target device is control device for rcopy push session (continued)

| | rcopy | state | : | | | | | | | | | | | | | | | |
|--|-------|----------------|---------|------------------|---------------|--------|----------------------|-----------|-------------------|--------|---------|--------------------|-----------------|----------|---------|--------------|-------------|---------|
| Clon e Con trol Ope rati on: | None | Create in prog | Created | Copy in progress | Copy on write | Copied | Recreate in progress | Recreated | Terminate in prog | Failed | Invalid | Verify in progress | Restore in prog | Restored | Precopy | Sync in prog | Syncronized | Stopped |
| Ter mina te | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| Rest ore | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| Split | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |

Clone target with rcopy pull

The following table identifies clone operations allowed when a TimeFinder Clone target device is the control device for a rcopy PULL session.

Table 67. TimeFinder Clone target device is control device for rcopy pull session

| | rcopy | y state | : | | | | | | | | | | | | | | | |
|--|-------|----------------|---------|------------------|---------------|--------|----------------------|-----------|-------------------|--------|---------|--------------------|-----------------|----------|---------|--------------|-------------|---------|
| Clo ne Con trol Ope rati on: | None | Create in prog | Created | Copy in progress | Copy on write | Copied | Recreate in progress | Recreated | Terminate in prog | Failed | Invalid | Verify in progress | Restore in prog | Restored | Precopy | Sync in prog | Syncronized | Stopped |
| Crea te/ recr eate | Y | | | | | | | | | | | | | Ya | | | | |
| Acti vate | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| Esta blish | Y | | | | | | | | | | | | | Ya | | | | |
| Ter mina te | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| Rest ore | Y | | | | | | | | | | | | | Y | | | | |
| Split | Y | Y | Y | Y | Y | Y | Y | Y | Y | Υ | Y | Y | Y | Y | Y | Y | Υ | Y |

a. Not supported with Donor Update.
